N94-25544 to N94-28398

The NASA STI Program ... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program plays a key part in helping NASA maintain this important role.

The NASA STI Program provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program is also NASA's institutional mechanism for disseminating the results of its research and development activities.

Specialized services that help round out the Program's diverse offerings include creating custom thesauri, translating material to or from 34 foreign languages, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program, you can:

- **Phone** the NASA Access Help Desk at (301) 621-0390
- **Fax** your question to the NASA Access Help Desk at (301) 621-0134
- **E-mail** your question via the **Internet** to help@sti.nasa.gov
- **Write** to:

NASA Access Help Desk

Linthicum Heights, MD 21090-2934

Scientific and Technical Aerospace Reports

STAR

Scientific and Technical Aerospace Reports (STAR), is published each month as a major product of the NASA Scientific and Technical Information (STI) Program.

Inside this issue you will find:

- **Front Matter** containing a typical citation and abstract sample explaining the standard format, including codes for ordering reports
- **An Abstract Section** containing citations and abstracts of reports and publications that provide comprehensive coverage of worldwide aerospace-related topics including aeronautics and space science technology. *STAR* lists published and publicly available reports entered into the NASA STI Database during the four weeks preceding publication of this issue. These citations and abstracts are listed by subject categories.
- **An Index Section**
  - Subject
  - Personal author
  - Corporate source
  - Contract number
  - Report number
- **An Appendix** containing a guide for ordering cited reports, registering with the NASA STI Program, and using the available products and services. Additionally, price schedules, phone numbers, and addresses are included in this information packed section.

NASA also sponsors the companion journal, *NASA Open Volumes on Aerospace (NOVA)*, which lists abstracts of the open literature on aerospace subjects available worldwide. *NOVA* is for internal NASA use only, available from the NASA Center for AeroSpace Information (CASI).

Entries found in *STAR* are available through the NASA online retrieval service, RECON, and through DIALOG as the Aerospace Database.

The NASA STI Program gathers information through national and international agreements and exchanges and makes this information available to the NASA community and to the public in many forms through various outlets.

For additional information on the NASA STI Program, call the NASA Access Help Desk at (301) 621-0390, or write to:

TABLE OF CONTENTS

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) 2641

02 AERODYNAMICS 2643
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also *34 Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY 2659
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION 2664
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE 2666
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION 2672
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER 2673
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL 2676
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) 2679
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) 2682
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS 2690
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) 2690
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES 2691
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION 2691
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING .. 2693
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—No abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE 2693
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance, 39 Structural Mechanics,* and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION 2698
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER 2699
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power, 28 Propellants and Fuels, 44 Energy Production and Conversion,* and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) 2704

24 COMPOSITE MATERIALS 2704
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY 2712
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS 2722
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS 2747
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS 2758
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING 2760
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology:*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) 2762
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR 2765
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety,* and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING 2779
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER 2789
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY 2809
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS 2815
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING 2821
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY 2834
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS 2836
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) .... N.A.

43 EARTH RESOURCES AND REMOTE SENSING 2847
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION 2853
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION 2865
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS 2876
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY 2891
Includes weather forecasting and modification.

48 OCEANOGRAPHY 2898
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) 2900

52 AEROSPACE MEDICINE 2908
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES 2937
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT 2940
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY 2944
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) 2945

60 COMPUTER OPERATIONS AND HARDWARE 2947
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE 2956
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS 2979
Includes computer networks and special application computer systems.

63 CYBERNETICS 2984
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS 2990
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY 3001
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS 3005
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS 3005
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

70 PHYSICS (GENERAL) 3007
For precision time and time interval (PTTI) see *35 Instrumentation and Photography*; for geophysics, astrophysics or solar physics see *46 Geophysics, 90 Astrophysics*, or *92 Solar Physics.*

71 ACOUSTICS 3009
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution.*

72 ATOMIC AND MOLECULAR PHYSICS 3011
Includes atomic structure, electron properties, and molecular spectra.

73 NUCLEAR AND HIGH-ENERGY PHYSICS 3031
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation.*

74 OPTICS 3033
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers.*

75 PLASMA PHYSICS 3041
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics.* For space plasmas see *90 Astrophysics.*

76 SOLID-STATE PHYSICS 3049
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers.*

77 THERMODYNAMICS AND STATISTICAL PHYSICS 3071
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and 34 *Fluid Mechanics and Heat Transfer.*

SOCIAL SCIENCES

80 SOCIAL SCIENCES (GENERAL) 3075
Includes educational matters.

81 ADMINISTRATION AND MANAGEMENT 3093
Includes management planning and research.

82 DOCUMENTATION AND INFORMATION SCIENCE 3095
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software.*

83 ECONOMICS AND COST ANALYSIS 3101
Includes cost effectiveness studies.

84 LAW, POLITICAL SCIENCE AND SPACE POLICY 3101
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.

85 URBAN TECHNOLOGY AND TRANSPORTATION 3102
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety, 16 Space Transportation,* and *44 Energy Production and Conversion.*

SPACE SCIENCES For related information see also *Geosciences.*

88 SPACE SCIENCES (GENERAL) .... **N.A.**

89 ASTRONOMY **3102**
Includes radio, gamma-ray, and infrared astronomy; and astrometry.

90 ASTROPHYSICS **3103**
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics.*

91 LUNAR AND PLANETARY EXPLORATION **3106**
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance.*

92 SOLAR PHYSICS **3110**
Includes solar activity, solar flares, solar radiation and sunspots. For related information see also *93 Space Radiation.*

93 SPACE RADIATION **3112**
Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine.* For theory see *73 Nuclear and High-Energy Physics.*

GENERAL

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

The application of advanced control concepts to air breathing engines may yield significant improvements in aircraft/engine performance and operability. Screening studies of advanced control concepts for air breathing engines were conducted by three major domestic aircraft engine manufacturers to determine the potential impact of concepts on turbine engine performance and operability. The purpose of the studies was to identify concepts which offered high potential yet may incur high research and development risk. A target suite of proposed advanced control concepts was formulated and evaluated in a two phase study to quantify each concept's impact on desired engine characteristics. To aid in the evaluation specific aircraft/engine combinations were considered: a Military High Performance Fighter mission, a High Speed Civil Transport mission, and a Civil Tiltrotor mission. Each of the advanced control concepts considered in the study are defined and described. The concept potential impact on engine performance was determined. Relevant figures of merit on which to evaluate the concepts are determined. Finally, the concepts are ranked with respect to the target aircraft/engine missions. A final report describing the screening studies was prepared by each engine manufacturer. Volume 1 of these reports describes the studies performed by Pratt & Whitney. Author (revised)

Scientific and Technical Aerospace Reports

A Monthly Publication of the National Aeronautics and Space Administration

01 AERONAUTICS (GENERAL)

N94-26212# National Aerospace Lab., Amsterdam (Netherlands).
TECHNICAL AND SCIENTIFIC RESEARCH FOR AERONAUTICS AND ASTRONAUTICS [TECHNISCH-WETENSCHAPPELIJK ONDERZOEK VOOR LUCHT- EN RUIMTEVAART]
Dec. 1992 18 p In DUTCH
(ETN-94-95392) Avail: CASI HC A03/MF A01

The activities of the National Aerospace Laboratory (NLR) are surveyed. In the field of aerodynamics research, activities are conducted in the low speed, high speed, supersonic, and Dutch-German wind tunnels, and in the laboratory for propulsion aerodynamics and aeroacoustics. In the domain of aircraft and helicopters, flight tests are performed, and research is conducted on two laboratory aircraft, a flight simulator, and an air traffic simulator. In the construction and materials division loading and fatigue of aircraft structures, as well as new materials, are investigated. In the field of astronautics, satellite positioning; microgravity; automation and robotics; temperature control; and Earth observation are studied. Information systems for aerospace applications are developed. Aerospace pollution and environmental control by aircrafts and satellites are investigated. ESA

SHAKE TEST RESULTS OF THE MDHC TEST STAND IN THE 40- BY 80-FOOT WIND TUNNEL
Benton H. Lau and Randall Peterson Jan. 1994 40 p
(RTOP 505-59-36)
(NASA-TM-108801; A-94029; NAS 1.15:108801) Avail: CASI HC A03/MF A01

A shake test was conducted to determine the modal properties of the MDHC (McDonnell Douglas Helicopter Company) test stand installed in the 40- by 80- Foot Wind Tunnel at Ames Research Center. The shake test was conducted for three wind-tunnel balance configurations with and without balance dampers, and with the snubber engagement to lock the balance frame. A hydraulic shaker was used to apply random excitation at the rotor hub in the longitudinal and lateral directions. A GenRad 2515 computer-aided test system computed the frequency response functions at the rotor hub and support struts. From these response functions, the modal properties, including the natural frequency, damping ratio, and mode shape were calculated. The critical modes with low damping ratios are identified as the test-stand second longitudinal mode for the dampers-off configuration, the test-stand yaw mode for the dampers-on configuration, and the test stand first longitudinal mode for the balance-frame locked configuration. FAA/NASA JOINT UNIVERSITY PROGRAM FOR AIR TRANSPORTATION RESEARCH, 1992-1993
Frederick R. Morrell, Comp. Feb. 1994 161 p Conference held in Athens, OH, 17-18 Jun. 1993; sponsored in part by FAA
(Grants NGL-22-009-640; NGL-31-001-252; NGR-36-009-017)
(NASA-CP-3246; NAS 1.55:3246; DOT/FAA/CT-94/03) Avail: CASI HC A08/MF A02

The research conducted during the academic year 1992-1993 under the FAA/NASA sponsored Joint University Program for Air Transportation Research is summarized. The year end review was held at Ohio University, Athens, Ohio, 17-18 June 1993. The Joint University Program is a coordinated set of three grants sponsored by the Federal Aviation Administration and NASA Langley Research Center, one each with the Massachusetts Institute of Technology, Ohio University, and Princeton University. Completed works, status reports, and annotated bibliographies are presented for research topics, which include navigation, guidance, and control theory and practice, aircraft performance, human factors and air traffic management. An overview of the year's activities for each university is also presented. For individual titles, see N94-27285 through N94-27298.

AN INVESTIGATION OF AIR TRANSPORTATION TECHNOLOGY AT THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY, 1992-1993 c03
Robert W. Simpson *In* NASA. Langley Research Center, FAA/NASA Joint University Program for Air Transportation Research, 1992-1993 Feb. 1994 p 3-8 (For primary document see N94-27284 07-01)
Avail: CASI HC A02/MF A02

An investigation of air transportation technology at MIT during 1992 - 1993 is presented. One completed project and two continuing research activities are under the sponsorship of the FAA/NASA Joint University Program. The completed project was on tracking aircraft around a turn with wind effects. Active research projects are on ASLOTS - an interactive adaptive system of automated approach spacing of aircraft and alerting in automated and datalink capable cockpits. Author (revised)

Avail: CASI HC A02/MF A02

Advances in avionics and display technology are significantly changing the cockpit environment in current transport aircraft. The MIT Aeronautical Systems Lab (ASL) developed a part-task flight simulator specifically to study the effects of these new technologies on flight crew situational awareness and performance. The simulator is based on a commercially-available graphics workstation, and can be rapidly reconfigured to meet the varying demands of experimental studies. The simulator was successfully used to evaluate graphical microbursts alerting displays, electronic instrument approach plates, terrain awareness and alerting displays, and ATC routing amendment delivery through digital datalinks. A DATA FUSION ALGORITHM FOR MULTI-SENSOR MICROBURST HAZARD ASSESSMENT c03
Craig R. Wanke and R. John Hansman *In* NASA. Langley Research Center, FAA/NASA Joint University Program for Air Transportation Research, 1992-1993 Feb. 1994 p 17-28 See also A92-55328 Submitted for

publication Sponsored in part by FAA (For primary document see N94-27284 07-01)
(Contract NGL-22-009-640; F19628-90-C-0002)
Avail: CASI HC A03/MF A02

A recursive model-based data fusion algorithm for multi-sensor microburst hazard assessment is described. An analytical microburst model is used to approximate the actual windfield, and a set of 'best' model parameters are estimated from measured winds. The winds corresponding to the best parameter set can then be used to compute alerting factors such as microburst position, extent, and intensity. The estimation algorithm is based on an iterated extended Kalman filter which uses the microburst model parameters as state variables. Microburst state dynamic and process noise parameters are chosen based on measured microburst statistics. The estimation method is applied to data from a time-varying computational simulation of a historical microburst event to demonstrate its capabilities and limitations. Selection of filter parameters and initial conditions is discussed. Computational requirements and datalink bandwidth considerations are also addressed. Author

FAULT DETECTION AND ISOLATION c38
Greg Bernath *In* NASA. Langley Research Center, FAA/NASA Joint University Program for Air Transportation Research, 1992-1993 Feb. 1994 p 35-43 Sponsored in part by FAA (For primary document see N94-27284 07-01)
(Grant NGR-36-009-17)
Avail: CASI HC A02/MF A02

In order for a current satellite-based navigation system (such as the Global Positioning System, GPS) to meet integrity requirements, there must be a way of detecting erroneous measurements, without help from outside the system. This process is called Fault Detection and Isolation (FDI). Fault detection requires at least one redundant measurement, and can be done with a parity space algorithm. The best way around the fault isolation problem is not necessarily isolating the bad measurement, but finding a new combination of measurements which excludes it. Author

IMPROVED MODELING OF GPS SELECTIVE AVAILABILITY c04
Michael S. Braasch, AnnMarie Fink, and Keith Duffus *In* NASA. Langley Research Center, FAA/NASA Joint University Program for Air Transportation Research, 1992-1993 Feb. 1994 p 45-54 Presented at the Institute of Navigation 1993 National Technical Meeting, San Francisco, CA, 20-22 Jan. 1993 (For primary document see N94-27284 07-01)
(Grant NGR-36-009-017)
Avail: CASI HC A02/MF A02

Selective Availability (SA) represents the dominant error source for stand-alone users of the Global Positioning System (GPS). Even for DGPS, SA mandates the update rate required for a desired level of accuracy in realtime applications. As was witnessed in the recent literature, the ability to model this error source is crucial to the proper evaluation of GPS-based systems. A variety of SA models were proposed to date; however, each has its own shortcomings. Most of these models were based on limited data sets or data which were corrupted by additional error sources. A comprehensive treatment of the problem is presented. The phenomenon of SA is discussed and a technique is presented whereby both clock and orbit components of SA are identifiable. Extensive SA data sets collected from Block 2 satellites are presented. System Identification theory then is used to derive a robust model of SA from the data. This theory also allows for the statistical analysis of SA. The stationarity of SA over time and across different satellites is analyzed and its impact on the modeling problem is discussed. Author

REALTIME MITIGATION OF GPS SA ERRORS USING LORAN-C c04
Soo Y. Braasch *In* NASA. Langley Research Center, FAA/NASA Joint University Program for Air Transportation Research, 1992-1993 Feb. 1994 p 55-61 Presented at the Wild Goose Association, Annual Convention and Technical Symposium, Birmingham, England, 24-27 Aug. 1992 Sponsored in part by FAA (For primary document see N94-27284 07-01)
(Grant NGR-36-009-17)
Avail: CASI HC A02/MF A02

The hybrid use of Loran-C with the Global Positioning System (GPS) was shown capable of providing a sole-means of enroute air radionavigation. By allowing pilots to fly direct to their destinations, use of this system is resulting in significant time savings and therefore fuel savings as well. However, a major error source limiting the accuracy of GPS is the intentional degradation of the GPS signal known as Selective Availability (SA). SA-induced position errors are highly correlated and far exceed all other error sources (horizontal position error: 100 meters, 95 percent). Realtime mitigation of SA errors from the position solution is highly desirable. How that can be achieved is discussed. The stability of Loran-C signals is exploited to reduce SA errors. The theory behind this technique is discussed and results using bench and flight data are given. Author (revised)

Avail: CASI HC A02/MF A02

The results of several case studies using the Global Positioning System coverage model developed at Ohio University are summarized. Presented are results pertaining to outage area, outage dynamics, and availability. Input parameters to the model include the satellite orbit data, service area of interest, geometry requirements, and horizon and antenna mask angles. It is shown for precision-landing Category 1 requirements that the planned GPS 21 Primary Satellite Constellation produces significant outage area and unavailability. It is also shown that a decrease in the user equivalent range error dramatically decreases outage area and improves the service availability. Author (revised)

GROUND STATION SITING CONSIDERATIONS FOR DGPS c04
James D. Waid *In* NASA. Langley Research Center, FAA/NASA Joint University Program for Air Transportation Research, 1992-1993 Feb. 1994 p 73-83 Presented at the Institute of Navigation 1993 National Technical Meeting, San Francisco, CA, 20-22 Jan. 1993 Sponsored in part by FAA (For primary document see N94-27284 07-01)
(Grants NAG1-1423; NGR-36-009-017)
Avail: CASI HC A03/MF A02

Aircraft guidance and positioning in the final approach and landing phases of flight requires a high degree of accuracy. The Global Positioning System operating in differential mode (DGPS) is being considered for this application. Prior to implementation, all sources of error must be considered. Multipath was shown to be the dominant source of error for DGPS and theoretical studies verified that multipath is particularly severe within the final approach and landing regions. Because of aircraft dynamics, the ground station segment of DGPS is the part of the system where multipath can most effectively be reduced. Ground station siting will be a key element in reducing multipath errors for DGPS system. This situation can also be improved by using P-code or narrow correlator C/A-code receivers along with a multipath rejecting antenna. A study of GPS multipath errors for a stationary DGPS ground station is presented. A discussion of GPS multipath error characteristics are presented along with some actual multipath data.

The data was collected for different ground station siting configurations using P-code, standard C/A-code, and narrow correlator C/A-code receiver architectures and two separate antenna constructions. Author (revised)

The Air Transportation Research Program at Princeton University proceeded along five avenues during the past year: (1) Flight Control System Robustness; (2) Microburst Hazards to Aircraft; (3) Wind Rotor Hazards to Aircraft; (4) Intelligent Aircraft/Airspace Systems; and (5) Aerospace Optical Communications. This research resulted in a number of publications, including theses, archival papers, and conference papers. An annotated bibliography of publications that appeared between June 1992 and June 1993 is included. The research that these papers describe was supported in whole or in part by the Joint University Program, including work that was completed prior to the reporting period. Author (revised)

OPTIMAL NONLINEAR ESTIMATION FOR AIRCRAFT FLIGHT CONTROL IN WIND SHEAR **c03**
Sandeep S. Mulgund *In* NASA. Langley Research Center, FAA/NASA Joint University Program for Air Transportation Research, 1992-1993 Feb. 1994 p 111-130 (For primary document see N94-27284 07-01)
Avail: CASI HC A03/MF A02

The most recent results in an ongoing research effort at Princeton in the area of flight dynamics in wind shear are described. The first undertaking in this project was a trajectory optimization study. The flight path of a medium-haul twin-jet transport aircraft was optimized during microburst encounters on final approach. The assumed goal was to track a reference climb rate during an aborted landing, subject to a minimum airspeed constraint. The results demonstrated that the energy loss through the microburst significantly affected the qualitative nature of the optimal flight path. In microbursts of light to moderate strength, the aircraft was able to track the reference climb rate successfully. In severe microbursts, the minimum airspeed constraint in the optimization forced the aircraft to settle on a climb rate smaller than the target. A tradeoff was forced between the objectives of flight path tracking and stall prevention. Author (revised)

AIR TRAFFIC MANAGEMENT AS PRINCIPLED NEGOTIATION BETWEEN INTELLIGENT AGENTS **c04**
J. P. Wangermann *In* NASA. Langley Research Center, FAA/NASA Joint University Program for Air Transportation Research, 1992-1993 Feb. 1994 p 131-140 (For primary document see N94-27284 07-01)
Avail: CASI HC A02/MF A02

The major challenge facing the world's aircraft/airspace system (AAS) today is the need to provide increased capacity, while reducing delays, increasing the efficiency of flight operations, and improving safety. Technologies are emerging that should improve the performance of the system, but which could also introduce uncertainty, disputes, and inefficiency if not properly implemented. The aim of our research is to apply techniques from intelligent control theory and decision-making theory to define an Intelligent Aircraft/Airspace System (IAAS) for the year 2025. The IAAS would make effective use of the technical capabilities of all parts of the system to meet the demand for increased capacity with improved performance. Author

OPTICAL COMMUNICATIONS FOR TRANSPORT AIRCRAFT **c32**
Robert Stengel *In* NASA. Langley Research Center, FAA/NASA Joint University Program for Air Transportation Research , 1992-1993 Feb. 1994 p 141-145 (For primary document see N94-27284 07-01)
Avail: CASI HC A01/MF A02

Optical communications for transport aircraft are discussed. The problem involves: increasing demand for radio-frequency bands from an enlarging pool of users (aircraft, ground and sea vehicles, fleet operators, traffic control centers, and commercial radio and television); desirability of providing high-bandwidth dedicated communications to and from every aircraft in the National Airspace System; need to support communications, navigation, and surveillance for a growing number of aircraft; and improved meteorological observations by use of probe aircraft. The solution involves: optical signal transmission support very high data rates; optical transmission of signals between aircraft, orbiting satellites, and ground stations, where unobstructed line-of-sight is available; conventional radio transmissions of signals between aircraft and ground stations, where optical line-of-sight is unavailable; and radio priority given to aircraft in weather. THE 1993 FEDERAL AVIATION ADMINISTRATION PLAN FOR RESEARCH, ENGINEERING AND DEVELOPMENT
Feb. 1994 198 p
Avail: CASI HC A09/MF A03

The FAA manages and operates the National Airspace System (NAS), a significant national resource. However, the demands on this system are continuously growing, and changing technologies provide the opportunity to dramatically improve system effectiveness and efficiency. To this end, the FAA's Research, Engineering, and Development (RE&D) Program is an investment in the future that will sustain the United States' preeminence in aviation throughout the world. Without this investment, the United States leadership would erode. Thus, the importance of aviation to the Nation mandates a comprehensive RE&D program to ensure both the safety of public air transportation and the fulfillment of national priorities and policy goals. Various aspects of the RE&D Program plan are discussed. Derived from text

EVALUATION OF A CONCENTRATION PROBE FOR APPLICATION IN A SUPERSONIC FLOW FIELD M.S. Thesis
John S. Alsup Dec. 1993 67 p
(AD-A273915; AFIT/GAE/ENY/93D-3) Avail: CASI HC A04/MF A01

Aspirating, concentration probes are used to measure binary gas concentrations in a supersonic flow. In the past, a tank discharge method has been used to calibrate concentration probes. An alternate calibration method has been developed and tested on a probe in a steady, subsonic/sonic flow. This study evaluated the calibration and performance of a concentration probe in a steady, supersonic flow over a range of mixture ratios of air and helium. The results of this study and a comparison of the two calibration methods are presented. DTIC

CALCULATION OF VISCOUS DRAG OF TWO LOW ANGLE OF ATTACK SUPERCRITICAL PROFILES [BERAEKNING AV VISKOESA MOTSTAANDET FOER TVAA SUPERKRISTISKA PROFILER VID LAAGA ANFALLSVINKLAR]

S. Paaso 3 May 1984 40 p In SWEDISH Sponsored by Foersvarets Materialverk, Stockholm, Sweden
(FFA-TN-1984-22; ETN-94-93902) Avail: CASI HC A03/MF A01

Two supercritical profile calculations were carried out to determine which profile is better at subcritical Mach numbers. The tests were carried out on natural scale Reynolds numbers and on prototype Reynolds numbers. The NACA 64A010 profile was included in the test to check control the results obtained by the programs and the formulas used and to compare the supercritical profiles with a NACA type profile. The supercritical profiles appeared to have similar drag curves, and the NACA 64A010 showed lower drag at low angle of attack. The prototype drag profiles differ a little in relation to the natural profile. ESA

PERFORMANCE OF RENORMALIZATION GROUP ALGEBRAIC TURBULENCE MODEL ON BOUNDARY LAYER TRANSITION SIMULATION Final Report

Kyung H. Ahn Feb. 1994 19 p
(Contract NAS3-25266; RTOP 535-03-10)
(NASA-CR-194466; E-8521; NAS 1.26:194466) Avail: CASI HC A03/MF A01

The RNG-based algebraic turbulence model, with a new method of solving the cubic equation and applying new length scales, is introduced. An analysis is made of the RNG length scale which was previously reported and the resulting eddy viscosity is compared with those from other algebraic turbulence models. Subsequently, a new length scale is introduced which actually uses the two previous RNG length scales in a systematic way to improve the model performance. The performance of the present RNG model is demonstrated by simulating the boundary layer flow over a flat plate and the flow over an airfoil. Author (revised)

CORRELATION OF AIRLOADS ON A TWO-BLADED HELICOPTER ROTOR

Francisco J. Fernandez and Wayne Johnson (Johnson Aeronautics, Palo Alto, CA.) Apr. 1993 26 p
(RTOP 505-59-36)
(NASA-TM-103982; A-93001; NAS 1.15:103982) Avail: CASI HC A03/MF A01

Airloads measured on a two-bladed helicopter rotor in flight during the Ames' Tip Aerodynamic and Acoustic Test are compared with calculations from a comprehensive helicopter analysis (CAMRAD/JA), and the pressures compared with calculations from a full-potential rotor code (FPR). The flight-test results cover an advance ratio range of 0.19 to 0.38. The lowest-speed case is characterized by the presence of significant blade-vortex interactions. Good correlation of peak-to-peak vortex-induced loads and the corresponding pressures is obtained. Results of the correlation for this two-bladed rotor are substantially similar to those for three- and four-bladed rotors, including the tip-vortex core size for best correlation, calculation of the peak-to-peak loads on the retreating side, and calculation of vortex iduced loads on inboard radial stations. The higher-speed cases are characterized by the presence of transonic flow on the outboard sections of the blade. Comparison of calculated and measured airloads on the advancing side is not considered appropriate because the presence of shocks makes chordwise integration of the measured data difficult. However, good correlation of the corresponding pressures is obtained. Author

COMMENTS REGARDING TWO UPWIND METHODS FOR SOLVING TWO-DIMENSIONAL EXTERNAL FLOWS USING UNSTRUCTURED GRIDS

W. L. Kleb Feb. 1994 29 p
(RTOP 232-01-04-04)
(NASA-TM-109078; NAS 1.15:109078) Avail: CASI HC A03/MF A01

Steady flow over the leading portion of a multicomponent airfoil section is studied using computational fluid dynamics (CFD) employing an unstructured grid. To simplify the problem, only the inviscid terms are retained from the Reynolds-averaged Navier-Stokes equations - leaving the Euler equations. The algorithm is derived using the finite-volume approach, incorporating explicit time-marching of the unsteady Euler equations to a time-asymptotic, steady-state solution. The inviscid fluxes are obtained through either of two approximate Riemann solvers: Roe's flux difference splitting or van Leer's flux vector splitting. Results are presented which contrast the solutions given by the two flux functions as a function of Mach number and grid resolution. Additional information is presented concerning code verification techniques, flow recirculation regions, convergence histories, and computational resources. Author (revised)

COMPUTATIONAL INVESTIGATION OF THE COMPRESSIBLE DYNAMIC STALL CHARACTERISTICS OF THE SIKORSKY SSC-A09 AIRFOIL M.S. Thesis

Thomas A. Johnston Sep. 1993 260 p
(AD-A274867) Avail: CASI HC A12/MF A03

Steady and unsteady two dimensional flowfield analysis was conducted for a Sikorsky SSC-A09 airfoil in compressible, high Reynolds number flows. Limited verification with experimental measurement was achieved. Computational methods included a steady, linear panel method with compressibility corrections; a laminar and turbulent boundary layer method; an unsteady, linear panel method; and a numerical solution method of the thin layer, compressible Navier-Stokes equations using a body-fitted C-type computational grid. The Baldwin-Lomax, two-layer, zero-equation turbulence model was used. Wind tunnel wall interference effects were ignored. Steady and unsteady airloads and instantaneous flow pictures are presented. In steady flow with little or no separation, computed lift, drag, pitching moment, and skin friction coefficients, as well as displacement thickness and boundary layer velocity profiles at several angles of attack, were generally found to be in good agreement with experimental data. MODELLING OF IONISATION REACTIONS AND OF THE RESULTING ELECTRIC FIELDS IN ONE-DIMENSIONAL HYPERSONIC SHOCK WAVES WITH THE DIRECT SIMULATION MONTE CARLO METHOD

M. A. Gallis and J. K. Harvey Jul. 1992 13 p
(Contract AT/2037/331) (ISSN 0308-7247)
(IC-Aero-92-01; ETN-94-95226) Avail: CASI HC A03/MF A01

The direct simulation Monte Carlo method is applied to ionized hypersonic rarefied flows. Calculations of the reaction rates are made with the method proposed by G.A. Bird and with the maximum entropy approach, which is extended to include reactions between monatomic and ionized particles. The assumptions made for the simulation of plasmas are discussed. A method for the treatment of electrons and the calculation of the electric field is described. The new approach for modeling plasmas is compared with the current modeling technique and both methods are compared with experimental data. Calculations for two normal shock wave test cases were performed: a real air test case at Mach 29 and an atomic hydrogen test case at Mach 60. The approach is in good agreement with the experimental data and offers a better explanation of the effects of nonequilibrium phenomena in the flow. ESA

LOW-SPEED PRESSURE DISTRIBUTION MEASUREMENTS OVER THE AFT-FUSELAGE, FINS, AND STABILATORS OF A 1/9TH SCALE F/A-18 WIND-TUNNEL MODEL

L. D. MacLaren and H. A. Quick Oct. 1993 93 p
(AD-A274870; ARL-RR-9; DODA-AR-008-367) Avail: CASI HC A05/MF A01

The steady-state aerodynamic pressure distribution over the aft fuselage, fin and stabilator of a 1/9th scale F/A-18 model has been measured for varying conditions at low speeds. Pressure distributions are presented in the form of a parametric study and the integration of the pressures to obtain total loads is included to indicate the overall effects of angle of attack, sideslip, stabilator deflection and the LEX fence. The results from these wind tunnel tests have illustrated the degree to which vortical flow dominates the conditions over the aft end of the aircraft, due to the presence of the primary LEX vortex and to local separations from sharp edged surfaces. A FINITE WAKE THEORY FOR TWO-DIMENSIONAL ROTARY WING UNSTEADY AERODYNAMICS M.S. Thesis

Mark A. Couch 23 Sep. 1993 69 p
(AD-A274921) Avail: CASI HC A04/MF A01

The unsteady aerodynamic forces and moments of an oscillating airfoil for the fixed wing case were determined by Theodorsen along with the development of a lift deficiency function. Loewy subsequently developed an analogous lift deficiency function for the rotary wing case in which there are an infinite number of layers of shed vorticity, or wakes, below the reference airfoil. With the advent of computer panel codes that calculate the time histories of the wakes generated by oscillating airfoils, a theory is developed for the rotary wing case in which there are a finite number of layers of shed vorticity below the reference airfoil. This theory includes a lift deficiency function that is completely analogous to Loewy and Theodorsen. It has long been recognized that an airfoil oscillating in pure plunge produces a propulsive force (Katzmayr effect). Garrick used Theodorsen's work to develop equations for the propulsive force that include the lift deficiency function as a parameter. When either Loewy's lift deficiency function or the finite wake lift deficiency function is used, the effect of the propulsive force is greatly enhanced with the proper phase relationship of the wakes. The finite wake theory along with Garrick's work is used to describe the performance characteristics of Higher Harmonic Control. Specifically for the OH-6A, coupled pitch-plunge motion results in a propulsive force that significantly reduces the rotor drag force. DTIC

A COMPARATIVE STUDY OF SERIAL AND PARALLEL AEROELASTIC COMPUTATIONS OF WINGS

Chansup Byun (MCAT Inst., Moffett Field, CA.) and Guru P. Guruswamy Jan. 1994 24 p
(RTOP 505-10-11)
(NASA-TM-108805; A-94039; NAS 1.15:108805) Avail: CASI HC A03/MF A01

A procedure for computing the aeroelasticity of wings on parallel multiple-instruction, multiple-data (MIMD) computers is presented. In this procedure, fluids are modeled using Euler equations, and structures are modeled using modal or finite element equations. The procedure is designed in such a way that each discipline can be developed and maintained independently by using a domain decomposition approach. In the present

parallel procedure, each computational domain is scalable. A parallel integration scheme is used to compute aeroelastic responses by solving fluid and structural equations concurrently. The computational efficiency issues of parallel integration of both fluid and structural equations are investigated in detail. This approach, which reduces the total computational time by a factor of almost 2, is demonstrated for a typical aeroelastic wing by using various numbers of processors on the Intel iPSC/860.

COMPUTATIONAL PREDICTION OF ISOLATED PERFORMANCE OF AN AXISYMMETRIC NOZZLE AT MACH NUMBER 0.90
John R. Carlson Feb. 1994 26 p
(RTOP 505-62-30-01)
(NASA-TM-4506; L-17248; NAS 1.15:4506) Avail: CASI HC A03/MF A01

An improved ability to predict external propulsive performance was incorporated into the three-dimensional Navier-Stokes code PAB3D. The improvements are the ability to account for skin friction and external pressure forces. Performance parameters for two axisymmetric supersonic cruise nozzle configurations were calculated to test the improved methodology. Internal and external flow-field regions were computed using a two-equation kappa-epsilon turbulent viscous-stress model. The computed thrust-minus-drag ratios were within 1 percent of the absolute level of experimental data and the trends of data were predicted accurately. The predicted trend of integrated nozzle pressure drag matched the trend of the integrated experimental pressure drag over a range of nozzle pressure ratios, but absolute drag levels were not accurately predicted.

THE MEASUREMENT OF DISTURBANCE LEVELS IN THE LANGLEY RESEARCH CENTER 20-INCH MACH 6 TUNNEL Final Report
P. C. Stainback and L. R. Kubendran Mar. 1994 23 p
(Contract NAS1-19320; RTOP 505-70-59-03)
(NASA-CR-4571; NAS 1.26:4571) Avail: CASI HC A03/MF A01

Constant-temperature anemometry was used to measure the disturbance levels in the Langley Research Center 20-inch Mach 6 Tunnel over a limited range of total pressures. The measurements were made using a dual wire probe where each wire was operated at a high but different overheat. The fluctuating voltages were digitized and a system of two equations was solved to obtain the instantaneous mass flow and total temperature fluctuations as a function of time. Statistical techniques were used to obtain statistical quantities of interest.

PRESSURE DISTRIBUTIONS ON A 0.02-SCALE SPACE SHUTTLE ORBITER NOSE AT MACH 21.5 IN HELIUM
George C. Ashby, Jr., Peter T. Bernot, and William C. Woods Jan. 1994 75 p
(RTOP 506-40-41-01)
(NASA-TM-4495; L-17038; NAS 1.15:4495) Avail: CASI HC A04/MF A01

Pressure distributions on a 0.02-scale model of the Space Shuttle orbiter forward fuselage were obtained in the 22-inch aerodynamic leg of the Langley Hypersonic Helium Tunnel Facility at a nominal free-stream Mach number of 21.5 and a ratio of specific heats of 1.67 for inclusion in the database of the Shuttle entry air data system (SEADS). The data were measured at model angles of attack of 0 deg to 50 deg in 5 deg increments for zero sideslip angle and at model sideslip angles of -5 deg to 5 deg for angles of attack equal to 5, 20, 35, and 40 deg. These data displayed trends similar to those observed in other wind tunnels at Mach 6 and 10 in air. Specifically noted is a shift in the location of the stagnation point at angles of attack above 15 deg; this effect did not, however, occur in flight. By comparison, the data obtained at Mach 6 in the Langley Hypersonic CF4 Tunnel, corresponding to a lower ratio of specific heats in the postshock region than those in helium and air, showed some reduction of the stagnation point shift at the higher angles of attack. The differences between flight and wind tunnel pressure distributions are believed due primarily to high-temperature gas chemistry effects in flight, which include lower effective specific heat ratios but which were not completely duplicated in the wind tunnels.

PILOTED SIMULATION STUDY OF AN ILS APPROACH OF A TWIN-PUSHER BUSINESS/COMMUTER TURBOPROP AIRCRAFT CONFIGURATION
Donald R. Riley, Jay M. Brandon, and Louis J. Glaab (Lockheed Engineering and Sciences Co., Hampton, VA.) Jan. 1994 120 p
(RTOP 535-03-01-03)
(NASA-TM-4516; L-17215; NAS 1.15:4516) Avail: CASI HC A06/MF A02

A six-degree-of-freedom nonlinear simulation of a twin-pusher, turboprop business/commuter aircraft configuration representative of the Cessna ATPTB (Advanced turboprop test bed) was developed for use in piloted studies with the Langley General Aviation Simulator. The math models developed are provided, simulation predictions are compared with with Cessna flight-test data for validation purposes, and results of a handling quality study during simulated ILS (instrument landing system) approaches and missed approaches are presented. Simulated flight trajectories, task performance measures, and pilot evaluations are presented for the ILS approach and missed-approach tasks conducted with the vehicle in the presence of moderate turbulence, varying horizontal winds and engine-out conditions. Six test subjects consisting of two research pilots, a Cessna test pilot, and three general aviation pilots participated in the study. This effort was undertaken in cooperation with the Cessna Aircraft Company.

Many of the aircraft battle damage repair methods involve application of a patch as thick as 12.7 mm over the damaged area to compensate for loss of structural and skin strength. The effect of such patches on the aerodynamics of the CF-18 aircraft wing is investigated. Boundary layer information was obtained by a series of wind tunnel tests on chamfered and unchamfered plates of various thicknesses at Reynolds numbers of 2,100 to 33,650. The results were expressed as polynomial curve fits with Delta H (the difference in shape factor across the patch edge) and (Delta Theta)/h (the ratio between the difference in momentum thickness across the patch edge and the step height or patch thickness) as functions of h divided by the initial momentum thickness. These plate correlation curves were then encoded into the Stalled Airfoil Modelling Package, which was used to analyze the effect of the patches on the flow over the CF-18 wing profile. The results revealed that even for the thickest patch (12.7 mm), the influence on lift is limited at low angles of attack but increases for angles of attack over 3 deg. The influence of the patches on drag is generally much greater and can double the drag coefficient with the thickest patches. A computer code listing is included.

EXPERIMENTAL AND THEORETICAL STUDY OF AERODYNAMIC CHARACTERISTICS OF SOME LIFTING BODIES AT ANGLES OF ATTACK FROM -10 DEGREES TO 53 DEGREES AT MACH NUMBERS FROM 2.30 TO 4.62
M. Leroy Spearman and Abel O. Torres Mar. 1994 25 p
(RTOP 505-69-20-01)
(NASA-TM-4528; L-17269; NAS 1.15:4528) Avail: CASI HC A03/MF A01

Lifting bodies are of interest for possible use as space transportation vehicles because they have the volume required for significant payloads and the aerodynamic capability to negotiate the transition from high angles of attack to lower angles of attack (for cruise flight) and thus safely reenter the atmosphere and perform conventional horizontal landings.

Results are presented for an experimental and theoretical study of the aerodynamic characteristics at supersonic speeds for a series of lifting bodies with 75 deg delta planforms, rounded noses, and various upper and lower surface cambers. The camber shapes varied in thickness and in maximum thickness location, and hence in body volume. The experimental results were obtained in the Langley Unitary Plan Wind Tunnel for both the longitudinal and the lateral aerodynamic characteristics. Selected experimental results are compared with calculated results obtained through the use of the Hypersonic Arbitrary-Body Aerodynamic Computer Program.

INFLUENCE OF THE TRANSONIC DOUBLET IN THE FARFIELD OF A LIFTING AIRFOIL

M. Mokry Oct. 1993 19 p
(IAR-AN-78; NRC-32161; CTN-94-61016) Avail: CASI HC A03/MF A01

In consideration of a need to extend the range of applicability of a linear method of correction for subsonic wind tunnel wall interference on airfoils to cases where the local supersonic pockets are extensive yet do not reach the upper and lower test section walls, a computational fluid dynamics based method for calculating the strength of the transonic doublet for a lifting, supercritical airfoil is presented. Experimentation with the finite volume, time-stepping solver of the Euler equation demonstrates that the computational domain used with the vortex boundary condition in farfield can be substantially reduced if the doublet term is also included. The increase of doublet strength due to nonlinear compressibility effects is a function of the far-upstream Mach number and lift coefficient, and is of an order of magnitude of the doublet strength based on the cross sectional area of the airfoil. The open-jet formula was shown to provide a sufficiently accurate incremental velocity correction to the previously corrected wind tunnel data by the linear subsonic method of Mokry and Ohman (1980).

FIBER-OPTIC-BASED LASER VAPOR SCREEN FLOW VISUALIZATION SYSTEM FOR AERODYNAMIC RESEARCH IN LARGER SCALE SUBSONIC AND TRANSONIC WIND TUNNELS

Gary E. Erickson and Andrew S. Inenaga (Aerometrics, Inc., Sunnyvale, CA.) Jan. 1994 69 p
(RTOP 505-68-30-03)
(NASA-TM-4514; L-17198; NAS 1.15:4514) Avail: CASI HC A04/MF A01

Laser vapor screen (LVS) flow visualization systems that are fiber-optic based were developed and installed for aerodynamic research in the Langley 8-Foot Transonic Pressure Tunnel and the Langley 7- by 10-Foot High Speed Tunnel. Fiber optics are used to deliver the laser beam through the plenum shell that surrounds the test section of each facility and to the light-sheet-generating optics positioned in the ceiling window of the test section. Water is injected into the wind tunnel diffuser section to increase the relative humidity and promote condensation of the water vapor in the flow field about the model. The condensed water vapor is then illuminated with an intense sheet of laser light to reveal features of the flow field. The plenum shells are optically sealed; therefore, video-based systems are used to observe and document the flow field. Operational experience shows that the fiber-optic-based systems provide safe, reliable, and high-quality off-surface flow visualization in smaller and larger scale subsonic and transonic wind tunnels. The design, the installation, and the application of the Langley Research Center (LaRC) LVS flow visualization systems in larger scale wind tunnels are highlighted. The efficiency of the fiber optic LVS systems and their insensitivity to wind tunnel vibration, the tunnel operating temperature and pressure variations, and the airborne contaminants are discussed.

WIND TUNNEL INVESTIGATION OF AN STOL AIRCRAFT MODEL: AN EFFECT OF ENGINE NACELLE SHAPE [STOL ZENKI MOKEI FUDO SHIKEN: ENJIN NASERU KEIJO KOKA]

Hitoshi Takahashi Jan. 1993 27 p In JAPANESE Prepared in cooperation with STOL Research Aircraft Group
(ISSN 0452-2982)
(NAL-TM-653; JTN-94-80621) Avail: CASI HC A03/MF A01

In initial wind tunnel tests on STOL experimental aircraft developed and researched by the National Aerospace Laboratory, a simulator engine nacelle which is longer and larger than that of 8 percent scales of FJR engines used in actual aircraft, was installed and tested on a model. To estimate ASKA's aerodynamics force data from wind tunnel data, the data was modified to take into account the different shapes of engine nacelle used in the simulated engine and that used in an 8 percent scale FJR (Fan Jet Research) engine. To confirm the adequacy of the modification, wind tunnel tests were conducted on a model with 8 percent scales FJR engine. From the comparison of the present test data with the initial test data and modified data, it was found that the correction of forces was overestimated and the correction of moments was fairly good.

HIGH-LIFT SYSTEM ANALYSIS METHOD USING UNSTRUCTURED MESHES

K. M. J. deCock 15 Sep. 1992 30 p Presented at the AGARD FDP Meeting and Symposium on High-Lift System Aerodynamics, Banff, Canada, 5-8 Oct. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NLR-TP-92351-U; ETN-94-95452; AD-B175579) Avail: CASI HC A03

A two dimensional high lift configuration analysis method is described. The flow model used is based on the Euler equations, discretized on unstructured meshes. The generation of the unstructured meshes is based on the principle of successive grid adaption with respect to the geometry. This approach makes later extension towards fully integrated grid adaption with respect to the solution straightforward. The main characteristics of the Euler solver are upwind flux difference splitting of the convective part of the Euler equations (second order accurate discretization in space) and four stage Runge-Kutta local time stepping. Results obtained with this analysis method are shown for the NACA0012 airfoil and three element airfoils.

CONTROL OF LEADING-EDGE SEPARATION ON AN AIRFOIL BY LOCALIZED EXCITATION [STEUERUNG DER VORDERKANTENABLOSUNG AN EINEM FLUGELPROFIL DURCH LOKALE ANREGUNG]

Alexander Dovgal (Academy of Sciences, USSR, Novosibirsk.) May 1993 56 p Sponsored by Alexander von Humbolt Foundation
(ISSN 0939-2963)
(DLR-FB-93-16; ETN-94-95494) Avail: CASI HC A04/MF A01

The experimental investigation on the control of the separated flow over a low Reynolds number airfoil placed at high angles of attack was carried out. To reduce the separated flow and improve the airfoil's performance, some kind of periodic forcing can be used. A version of this control method consists in excitation of the flow through a narrow slot at the surface of the model near its leading edge. Such a technique was examined with emphasis on its operational principles. The study continues others concerning the use of a localized excitation for the separation control and makes clear some details about mechanisms responsible for the effect of the excitation on a separating flow. METHODS IN UNSTEADY AERODYNAMICS [VERFAHREN IN DER INSTATIONAEREN AERODYNAMIK]
Wolfgang Geissler Jun. 1993 515 p In GERMAN
(ISSN 0939-2963)
(DLR-FB-93-21; ETN-94-95498) Avail: CASI HC A22/MF A04

Methods in unsteady aerodynamics used for the solution of aeroelastic and partly also for aeroacoustic problems are described. After a discussion of the necessary fundamental fluid mechanic inputs, the development and application of integral equation methods are described in two and three space dimensions for subsonic and supersonic flows. Unsteady airfoil flows as well as flows about wings, bodies, engine cowls, and aerodynamic interference problems between accelerated moving (oscillating) aircraft components are investigated. To handle nonlinear problems of unsteady flows with shock waves and/or with separation, corresponding numerical methods were discussed. In all cases comparisons with experimental data were performed. NORMAL FORCE OF LOW ASPECT RATIO CROPPED-DELTA WINGS AT PRE-STALL ANGLES OF ATTACK AND SUBSONIC SPEEDS
Dec. 1993 17 p
(ISSN 0141-397X)
(ESDU-93034; ISBN-0-85679-887-8) Avail: ESDU

ESDU 93034 presents graphical data at taper ratios of 0, 0.5, and 1, applying at Mach numbers of 0.5 and below, at at Mach numbers of 0.8 and 0.95. They were obtained by correlating experimental data drawn from the literature for delta, cropped delta, and rectangular thin, uncambered and untwisted, sharp-edge wings of aspect ratio from 0.2 to 4 and apply up to angles of attack of 35 degrees, that is up to the stall. Below an angle of attack of 5 degrees, the normal force is obtained from the normal-force curve slop at zero angle of attack, and a graph is provided for that based on the method of ESDU 70011. The accuracy of the method is within 5%. ESDU

CONTRIBUTION OF BODY-MOUNTED FINS AND TAILPLANES TO LATERAL DERIVATIVES DUE TO SIDESLIP AT SUBSONIC SPEEDS FOR GENERAL BODY WIDTH TO HEIGHT RATIO
Apr. 1993 35 p
(ISSN 0141-397X)
(ESDU-93007; ISBN-0-85679-859-2) Avail: ESDU

ESDU 93007 applies to single or twin fins on aircraft at angles of attack up to 6 degrees and angles of sideslip up to 4 degrees. It treats a wider range of body height/width ratios than ESDU 82010 which deals with the single body mounted fin for geometries typical of transport aircraft where body height/width ratio is close to one. The fin sideforce is calculated by applying a semi-empirical interference factor to a basic lift-curve slope estimated from ESDU 70011 for the wing obtained when the fin is reflected about its root chord. The interference factor takes account of body, wing and tailplane interference, and three factors are provided depending on the relative positions of all lifting surfaces. For twin fins a further empirical factor is applied. Yawing and rolling moments follow once the point of action of the sideforce is known; the point empirically determined in ESDU 82010 based on an assumed elliptical loading along the fin quarter-chord line was found to be satisfactory here as well. Methods are also given for estimating the small contributions to the yawing and rolling moments from a body-mounted tailplane. Plots of predicted results against experimental data extracted from 24 sources in the literature (together with some unpublished results) show the sideforce, yawing moment and rolling moment derivatives to be estimated within 0.08, 0.04 and 0.02 respectively. The ranges of geometry covered by the test data are tabulated, and two fully worked examples illustrate the use of the methods. ESDU

LIFT-CURVE SLOPE FOR STRUCTURAL RESPONSE CALCULATIONS
Dec. 1993 20 p
(ISSN 0143-2702)
(ESDU-93013; ISBN-0-85679-865-7) Avail: ESDU

ESDU 93013 provides data for the rate of change with wind direction of the force components in the directions of the principal axes of the structure. The values are an essential input to the calculation methods of ESDU 89049 and 91010 for calculating the response of structures to buffeting by across-wind turbulence and the response in galloping, respectively. For building shapes, essentially prismatic blocks with only small edge rounding, tables give values for the two components for a range of cross-section aspect ratios and three levels of along-wind turbulence intensity; the values were obtained from the force correlations in ESDU 80003. For beam sections, values for both components are given for angle, channel, I-, H-, T- and X-sections and for two channel sections back-to-back; the data were obtained from the correlations in ESDU 82007. For bridge decks, data extracted from the literature are given for the across-wind component (that is, the rate of change of lift with wind direction) for over 30 different types of bridge. Where available, data are included on the solidity and aspect ratio of the barrier and on the turbulence levels in the original wind-tunnel tests. ESDU

NONEQUILIBRIUM RADIATION AND CHEMISTRY MODELS FOR AEROCAPTURE VEHICLE FLOWFIELDS Final Report
Leland A. Carlson Mar. 1994 189 p
(Grant NAG1-1003)
(NASA-CR-195706; NAS 1.26:195706; TAMRF-6382-94-01) Avail: CASI HC A09/MF A02

The primary accomplishments of the project were as follows: (1) From an overall standpoint, the primary accomplishment of this research was the development of a complete gasdynamic-radiatively coupled nonequilibrium viscous shock layer solution method for axisymmetric blunt bodies. This method can be used for rapid engineering modeling of nonequilibrium re-entry flowfields over a wide range of conditions. (2) Another significant accomplishment was the development of an air radiation model that included local thermodynamic nonequilibrium (LTNE) phenomena. (3) As part of this research, three electron-electronic energy models were developed. The first was a quasi-equilibrium electron (QEE) model which determined an effective free electron temperature and assumed that the electronic states were in equilibrium with the free electrons. The second was a quasi-equilibrium electron-electronic (QEEE) model which computed an effective electron-electronic temperature. The third model was a full electron-electronic (FEE) differential equation model which included convective, collisional, viscous, conductive, vibrational coupling, and chemical effects on electron-electronic energy. (4) Since vibration-dissociation coupling phenomena as well as vibrational thermal nonequilibrium phenomena are important in the nonequilibrium zone behind a shock front, a vibrational energy and vibration-dissociation coupling model was developed and included in the flowfield model. This model was a modified coupled vibrational dissociation vibrational (MCVDV) model and also included electron-vibrational coupling. (5) Another accomplishment of the project was the usage of the developed models to investigate radiative heating. (6) A multi-component diffusion model which properly models the multi-component nature of diffusion in complex gas mixtures such as air, was developed and incorporated into the blunt body model. (7) A model was developed to predict the magnitude and characteristics of the shock wave precursor ahead of vehicles entering the Earth's atmosphere. (8) Since considerable data exists for radiating nonequilibrium flow behind normal shock waves, a normal shock wave version of the blunt body code was developed. (9) By comparing predictions from the models and codes with available normal shock data and the flight data of Fire II, it is believed that the developed flowfield and nonequilibrium radiation models have been essentially validated for engineering applications. AN INITIAL INVESTIGATION INTO METHODS OF COMPUTING TRANSONIC AERODYNAMIC SENSITIVITY COEFFICIENTS Final Report
Leland A. Carlson Mar. 1994 118 p
(Grant NAG1-793)

(NASA-CR-195705; NAS 1.26:195705; TAMRF-5802-94-01) Avail: CASI HC A06/MF A02

The primary accomplishments of the project are as follows: (1) Using the transonic small perturbation equation as a flowfield model, the project demonstrated that the quasi-analytical method could be used to obtain aerodynamic sensitivity coefficients for airfoils at subsonic, transonic, and supersonic conditions for design variables such as Mach number, airfoil thickness, maximum camber, angle of attack, and location of maximum camber. It was established that the quasi-analytical approach was an accurate method for obtaining aerodynamic sensitivity derivatives for airfoils at transonic conditions and usually more efficient than the finite difference approach. (2) The usage of symbolic manipulation software to determine the appropriate expressions and computer coding associated with the quasi-analytical method for sensitivity derivatives was investigated. Using the three dimensional fully conservative full potential flowfield model, it was determined that symbolic manipulation along with a chain rule approach was extremely useful in developing a combined flowfield and quasi-analytical sensitivity derivative code capable of considering a large number of realistic design variables. (3) Using the three dimensional fully conservative full potential flowfield model, the quasi-analytical method was applied to swept wings (i.e. three dimensional) at transonic flow conditions. (4) The incremental iterative technique has been applied to the three dimensional transonic nonlinear small perturbation flowfield formulation, an equivalent plate deflection model, and the associated aerodynamic and structural discipline sensitivity equations; and coupled aeroelastic results for an aspect ratio three wing in transonic flow have been obtained. PROGRAM FOR CALCULATION OF MAXIMUM LIFT COEFFICIENT OF PLAIN AEROFOILS AND WINGS AT SUBSONIC SPEEDS

Aug. 1993 27 p
(ISSN 0141-397X)
(ESDU-93015; ISBN-0-85679-867-3) Avail: ESDU

ESDU 93015 introduces a Fortran program for aerofoils and wings without high-lift devices. For aerofoils the method of ESDU 84026 is used, which itself relies on the prediction of lift-curve slope from ESDU Aero W.01.01.05. Sections can have a rough leading-edge (such as would result from ice formation) or a smooth leading-edge. The program applies a test to the section geometry data to determine whether the section has rear loading and trailing-edge thickness; such modern aerofoils have a higher maximum lift. If the user has not specified the section is modern, and the test shows that it is, the program will compute on that basis and print a warning. For wings the method of ESDU 89034 is used and assumes smooth leading-edges. The program first finds the spanwise location of peak loading for the given planform at each Mach number. The section geometry at each of those locations is then input, together with a camber and twist distribution which may be linear or non-linear. In the latter case, aerofoil data are also required at the wing root and at 2/3 of span to calculate the zero lift incidence at those two sections. The input and output formats are fully explained and illustrated with worked examples. The program is provided on disc (uncompiled) in the software volume as ESDUpac A9315. ESDU

N94-28091 ESDU International Ltd., London (England).

COMPUTATION OF STATIC PRESSURE DOWNSTREAM OF A NORMAL SHOCK FOR HYPERSONIC FLIGHT (AMBIENT TEMPERATURE KNOWN)

Aug. 1993 16 p
(ISSN 0141-4054)
(ESDU-93020; ISBN-0-85679-873-8) Avail: ESDU

ESDU 93020 is ancillary to and is for use in conjunction with ESDU 88025, which provides a definitive method for deriving primary air-data parameters in hypersonic flight with excellent precision, provided an accurate value of static pressure is available. ESDU 93020 provides an accurate means of deriving this static pressure without relying on a static pressure system. It is not possible to evaluate the relationship between the sensed static pressure and the real ambient pressure when the air is calorically and thermally imperfect as it is behind the shock in hypersonic flight. The static pressure is then used in the method of ESDU 88025. ESDU 93020 uses the ratio of static to total pressures behind a normal (detached) shock which is given in terms of quantities tabulated in ESDU 88025 and requires a knowledge of total temperature and pressure. However, it also requires a knowledge of the ambient temperature and the lapse rate, either from meteorological balloons or satellite observation, although an accuracy of 4 or 5 K for ambient temperature will be satisfactory. A worked example illustrates the use of the method for the same flight conditions used in the example in ESDU 88025. ESDU

N94-28140 ESDU International Ltd., London (England).

WING LIFT INCREMENT AT ZERO ANGLE OF ATTACK DUE TO DEPLOYMENT OF SINGLE-SLOTTED FLAPS AT LOW SPEEDS

Dec. 1993 17 p Supersedes Aero-F.01.01.08
(ISSN 0141-397X)
(ESDU-93019; Aero-F.01.01.08; ISBN-0-85679-872-X) Avail: ESDU

ESDU 93019 presents an empirical method that depends on determining the increment for an aerofoil representative of the wing and applying factors to allow for three-dimensional and part-span effects. ESDU 86033 is used to predict the increment for the aerofoil, depending on the extended deployed chord, and the section included trailing-edge angle. That increment is factored by the ratio of the wing to aerofoil lift curve slopes obtained respectively from ESDU 70011 and Aero W.01.01.05, thereby, accounting for aspect ratio, taper, and sweep effects. Finally, part-span factors are applied that depend on the spanwise center of pressure of the loading due to incidence obtained from ESDU 83040. The range of parameters for which the method was validated are tabulated and include aspect ratios of 3.7 to 9, taper ratios from 0.2 to 1, leading-edge sweep up to 48 degrees, Mach numbers up to 0.26, and flap deflections of 10 to 45 degrees. Sketches show the correlation between experimental results drawn from the literature and predicted results; for all results, 90 percent were correlated within 15 percent while for part-span cases alone 80 percent of the data were correlated to within 5 percent. A worked example illustrates the use of the method. ESDU

N94-28144 ESDU International Ltd., London (England).

EXAMPLES OF EXCRESCENCE DRAG PREDICTION FOR TYPICAL WING COMPONENTS OF A SUBSONIC TRANSPORT AIRCRAFT AT THE CRUISE CONDITION

Dec. 1993 88 p
(ISSN 0141-397X)
(ESDU-93032; ISBN-0-85679-885-1) Avail: ESDU

ESDU 93032 illustrates the application to a real situation of the ESDU data on drag due to cavities, grooves, steps, ridges, and control gaps, and the drag magnification factor applied to them to account for the effects of a nonuniform pressure distribution. An aileron, a leading-edge slat, a spoiler, a trailing-edge flap, a typical fuel tank access door, and a main undercarriage unit door are considered. For each component the necessary information is provided: graphs of flow data (Mach number, velocity, temperature, and density) and a detailed sketch showing all dimensions and sealing arrangement. Two cases are treated for each component: an ideal state with airtight seals and no avoidable surface mismatches, and a situation with poor sealing or surface mismatches. The comparison between results for the two cases illustrates the penalties from poor sealing or fits, and the possible effects of in-service deterioration. Detailed calculations are given for one feature of each excrescence, and the complete drag calculation is summarized in tabular form. The major contributions to the drag of each component are discussed and methods of reducing them are considered. The results from all the examples are finally reviewed to indicate the basic principles in design for low excrescence drag, and, to show their relative importance, the contribution of each component is expressed as a fraction of a plausible total excrescence drag for the wing. HIGH-SPEED RESEARCH: SONIC BOOM, VOLUME 1

Thomas A. Edwards, ed. Feb. 1994 231 p Conference held in Moffett Field, CA, 12-14 May 1993; sponsored by NASA
(RTOP 537-03-21)
(NASA-CP-10132; A-94045; NAS 1.55:10132) Avail: CASI HC A11/MF A03

The second High-Speed Research Program Sonic Boom Workshop was held at NASA Ames Research Center May 12-14, 1993. The workshop was organized into three sessions dealing with atmospheric propagation, acceptability, and configuration design. Volume 1 includes papers on atmospheric propagation and acceptability studies. Significant progress is noted in these areas in the time since the previous workshop a year earlier. In particular, several papers demonstrate an improved capability to model the effect of atmospheric turbulence on sonic booms. This is a key issue in determining the stability and acceptability of shaped sonic booms. In the area of acceptability, the PLdB metric has withstood considerable scrutiny and is validated as a loudness metric for a wide variety of sonic boom shapes. The differential loudness of asymmetric sonic booms is better understood, too. For individual titles, see N94-28189 through N94-28198.

PROGRESS IN MODELING ATMOSPHERIC PROPAGATION OF SONIC BOOMS

Allan D. Pierce *In* NASA. Ames Research Center, High-Speed Research: Sonic Boom, Volume 1 Feb. 1994 p 1-18 (For primary document see N94-28188 07-02)

Avail: CASI HC A03/MF A03

The improved simulation of sonic boom propagation through the real atmosphere requires greater understanding of how the transient acoustic pulses popularly termed sonic booms are affected by humidity and turbulence. A realistic atmosphere is invariably somewhat turbulent, and may be characterized by an ambient fluid velocity v and sound speed c that vary from point to point. The absolute humidity will also vary from point to point, although possibly not as irregularly. What is ideally desired is a relatively simple scheme for predicting the probable spreads in key sonic boom signature parameters. Such parameters could be peak amplitudes, rise times, or gross quantities obtainable by signal processing that correlate well with annoyance or damage potential. The practical desire for the prediction scheme is that it require a relatively small amount of knowledge, possibly of a statistical nature, concerning the atmosphere along, the propagation path from the aircraft to the ground. The impact of such a scheme, if developed, implemented, and verified, would be that it would give the persons who make planning decisions a tool for assessing the magnitude of environmental problems that might result from any given overflight or sequence of overflights. The technical approach that has been followed by the author and some of his colleagues is to formulate a hierarchy of simple approximate models based on fundamental physical principles and then to test these models against existing data. For propagation of sonic booms and of other types of acoustic pulses in nonturbulent model atmospheres, there exists a basic overall theoretical model that has evolved as an outgrowth of geometrical acoustics. This theoretical model depicts the sound as propagating within ray tubes in a manner analogous to sound in a waveguide of slowly varying cross-section. Propagation along the ray tube is quasi-one-dimensional, and a wave equation for unidirectional wave propagation is used. A nonlinear term is added to this equation to account for nonlinear steepening, and the formulation has been carried through to allow for spatially varying sound speed, ambient density, and ambient wind velocities. The model intrinsically neglects diffraction, so it cannot take into account what has previously been mentioned in the literature as possibly important mechanisms for turbulence-related distortion. The model as originally developed could predict an idealized N-waveform which often agrees with data in terms of peak amplitude and overall positive phase duration. It is possible, moreover, to develop simple methods based on the physics of relaxation processes for incorporating molecular relaxation into the quasi-one-dimensional model of nonlinear propagation along ray tubes. IMPLICATIONS FOR HIGH SPEED RESEARCH: THE RELATIONSHIP BETWEEN SONIC BOOM SIGNATURE DISTORTION AND ATMOSPHERIC TURBULENCE

Victor W. Sparrow and Thomas A. Gionfriddo *In* NASA. Ames Research Center, High-Speed Research: Sonic Boom, Volume 1 Feb. 1994 p 19-64 (For primary document see N94-28188 07-02)

In this study there were two primary tasks. The first was to develop an algorithm for quantifying the distortion in a sonic boom. Such an algorithm should be somewhat automatic, with minimal human intervention. Once the algorithm was developed, it was used to test the hypothesis that the cause of a sonic boom distortion was due to atmospheric turbulence. This hypothesis testing was the second task. Using readily available sonic boom data, we statistically tested whether there was a correlation between the sonic boom distortion and the distance a boom traveled through atmospheric turbulence. Theoretical research was carried out to study the effect of free-stream turbulence on sonic boom pressure fields. A new transonic small-disturbance model to analyze the interactions of random disturbances with a weak shock was developed. The model equation has an extended form of the classic small-disturbance equation for unsteady transonic aerodynamics. An alternative approach shows that the pressure field may be described by an equation that has an extended form of the classic nonlinear acoustics equation that describes the propagation of sound beams with narrow angular spectrum. The model shows that diffraction effects, nonlinear steepening effects, focusing and caustic effects and random induced vorticity fluctuations interact simultaneously to determine the development of the shock wave in space and time and the pressure field behind it. A finite-difference algorithm to solve the mixed type elliptic-hyperbolic flows around the shock wave was also developed. Numerical calculations of shock wave interactions with various deterministic and random fluctuations will be presented in a future report. Author (revised)

SONIC BOOM PROPAGATION THROUGH TURBULENCE: A RAY THEORY APPROACH

Leick D. Robinson *In* NASA. Ames Research Center, High-Speed Research: Sonic Boom, Volume 1 Feb. 1994 p 93-107 (For primary document see N94-28188 07-02)

Avail: CASI HC A03/MF A03

A ray theory approach is used to examine the propagation of sonic booms through a turbulent ground layer, and to make predictions about the received waveform. The rays are not propagated one at a time, as is typical in ray theory; instead, sufficient rays to represent a continuous wave front are propagated together. New rays are interpolated as needed to maintain the continuity of the wave front. In order to predict the received boom signature, the wave front is searched for eigenrays after it has propagated to the receiver. The Comte-Bellot turbulence model is used to generate an instantaneous 'snapshot' of the turbulent field. The transient acoustic wave is assumed to be sufficiently short in duration such that the time-dependacde of the turbulent field may be neglected. Author (revised)

THE PROPAGATION OF SPARK-PRODUCED N WAVES THROUGH TURBULENCE

Bart Lipkens *In* NASA. Ames Research Center, High-Speed Research: Sonic Boom, Volume 1 Feb. 1994 p 109-132 (For primary document see N94-28188 07-02)

Avail: CASI HC A03/MF A03

A model experiment was designed and built to simulate the propagation of sonic booms through atmospheric turbulence. The setup of the model experiment is described briefly. Measurements of the N waves after they propagated across the turbulent velocity field reveal the same waveform distortion and change in rise time as for sonic booms. The data from the model experiment is used to test sonic boom models. Some models yield predictions for the waveform distortion, while others give estimates of the rise time of the sonic booms. A new theoretical model for the propagation of plane N waves through a turbulent medium is described.

The purpose of this paper is to summarize the most recent sonic boom laboratory studies performed at NASA-LaRC using the Sonic Boom Simulator. The first used synthesized idealized outdoor boom shapes which were filtered to represent booms heard inside a house. The test explored the efficacy of various metrics in assessing both loudness and annoyance responses to these booms. The second test investigated the effects of adding single reflections to idealized boom signatures, and the third compared booms recorded from real aircraft with idealized boom signatures to determine if subjects rated the real booms differently. In these studies, as in previous studies performed at NASA-LaRC, there was a continuing effort to evaluate metrics for predicting the subjective effects of sonic booms. Author (revised)

Several scientific, regulatory, and policy-coordinating bodies have developed methods for predicting community response to sonic booms. The best known of these is the dosage-response relationship of Working Group 84 of the National Academy of Science's Committee on Hearing, Bioacoustics and Biomechanics. This dosage-response relationship between C-weighted DayNight Average Sound Level and the prevalence of annoyance with high energy impulsive sounds was derived from limited amounts of information about community response to regular, prolonged, and expected exposure to artillery and sonic booms. U.S. Army Regulation 201 adapts this approach to predictions of the acceptability of impulsive noise exposure in communities. This regulation infers equivalent degrees of effect with respect to a well known dosage-response relationship for general (nonimpulsive) transportation noise. Differences in prevalence of annoyance predicted by various relationships lead to different predictions of the compatibility of land uses with sonic boom exposure. An examination of these differences makes apparent several unresolved issues in current practice for predicting and interpreting the prevalence of annoyance due to sonic boom exposure. A wind tunnel investigation was carried out to assess the aerodynamic interactions of the propeller slipstream on a three dimensional wing of supercritical design, and to determine the flow characteristics immediately behind the propeller plane. A semispan model comprising a fuselage, zero sweep wing, and a powered nacelle was tested, to be representative of a generic model suitable for the design and performance analysis of a possible future transport aircraft. The wing was instrumented with 288 surface pressure orifices and the wing pressure distributions were measured and integrated to yield lift, drag, and pitching moment coefficients. Corrections for wall interference were made using the software package of Mokry et al (1987). Flow characteristics behind the propeller plane were determined using special five-hole probe rakes. The balance data indicated that the model force and moment coefficients were significantly affected by the propeller action. The slipstream was found to have at least an equally large effect as the propeller thrust negating the thrust component on the pitching moment. An increase in section lift coefficient was indicated for the propeller upwash zone and a decrease in the downwash zone. The propeller and its slipstream had little effect on the shock locations on the upper wing when the flow became supercritical. Author (CISTI)

Flow field data were acquired in the near slipstream of an 8-bladed 15-in. diameter propfan, nacelle mounted on a half-model wing configuration in a wind tunnel. The generally accepted five-hole probe technique was employed for the flow field measurements, with the probe heads located behind the propeller plane. Data were acquired at Mach numbers 0.6 and 0.7 at a Reynolds number of about 7.5 million. The propeller rpm and model angle of attack were varied moderately at each Mach number. It is shown that the radial flow angle was dominated by the nacelle geometry and virtually unaffected by the propeller action. The distribution of the circumferential flow angle and the propeller induced swirl angle was very non-uniform, mainly due to the effect of wing-lift induced upwash. The total pressure distribution was similar in character to that of the swirl angle. The Mach number losses or gains due to the action of the propeller were small. The value of the power coefficient derived from the motor power, with the survey rakes mounted, was found to be sensitive to rake orientation. A single-probe measurement investigation revealed that for the blade loading conditions used, probe arrangement indeed had a significant interference effect on the circumferential flow angle. For higher blade loadings, the probe interference effects became negligible. Author (CISTI)

ASSESSING THE EFFECTS OF TUNED VIBRATION ABSORBERS (TVAs) ON INTERIOR CABIN NOISE LEVELS: A CORRELATION BETWEEN ANALYTICAL ACOUSTIC PREDICTIONS AND FLIGHT TEST MEASUREMENTS **c71**
Ralph Garcea *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 9-12 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

Analytical predictions of interior noise levels were correlated with actual flight test data obtained during a program undertaken to develop the proper design and optimal distribution of tuned vibration absorbers for the Dash-8 Series 300 aircraft. The measured operational deflection shape data of the fuselage structure were used as boundary conditions for the interior noise predictions using a boundary element method model and finite element method modal analysis. The analytical modelling procedures used to represent the interior cavity, the underlying assumptions on which the predictions were based, and the correlations obtained are reported. The main assumptions were that the fuselage model was closed with rigid end caps (simulating cabin bulkheads) and that the interior acoustic field was solely due to the vibration of the fuselage skin. In addition, a panel acoustic power contribution analysis was performed to identify the most heavily radiating panels. For example, the skin panels between frames 271 and 290 contributed 62 percent of the total radiated output power at 60 Hz. The flight data and noise predictions correlated well, showing decreased sound pressure levels within the cabin interior due to the effects of the tuned vibration absorbers. Author (CISTI)

PROPELLER OFF-AXIS LOADS DUE TO THRUST AXIS INCIDENCE AND NACELLE MAGNUS FORCE **c07**
P. Vyriotes, J. Petzke, and D. Barber *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 13-16 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

Propeller and nacelle loads for various configurations were measured in a series of wind tunnel tests. Wind tunnel data for four- and six-blade research propellers demonstrated the influence of blade angle, advance ratio, and model incidence on propeller shaft loads and nacelle force. Complementary theoretical estimates of the off-axis hub loads were performed using panel and lifting line theories. Favorable correlation between experimental and theoretical data was demonstrated. The test data showed that when the propeller was yawed, the swirl induced nacelle force was comparable in magnitude, but perpendicular to, the propeller shaft side force. The effect of an inlet on the propeller shaft loads was also examined. For an axisymmetric nacelle, the normal force and yawing moment acting on the propeller shaft remained approximately zero. The presence of a pitot inlet nacelle immediately behind the propeller induced an additional normal force and yawing moment on the propeller shaft which was independent of the nacelle yaw angle. If the propeller and nacelle were then pitched, the intake induced loads would contribute to the shaft loads. If the propeller and nacelle were yawed, the intake induced force would act in the same sense as the nacelle force. Author (CISTI)

EFFECT OF SURFACE FINISH ON TURBINE AIRFOIL CASCADE LOSSES **c07**
Rama Radmard, Peter J. Turyk (Pratt and Whitney Aircraft of Canada Ltd., Mississauga, Ontario.), and William E. Carscallen (National Research Council of Canada, Ottawa, Ontario.) *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 17-20 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

The importance of surface finish on airfoil pressure loss measurement was investigated in a four-passage transonic cascade at nominal exit Mach numbers of 0.7, 0.9, and 1.1. Stagnation pressure and flow angles were measured one quarter chord downstream of the airfoil row using a yawing wedge probe. Three airfoil profiles were used: a baseline airfoil typical of a midsection of a high pressure turbine first vane, plus two thicker airfoils of 27 percent and 48 percent maximum thickness to true chord ratio. The thicker airfoils exhibit lower total pressure loss than the baseline at all three exit conditions. Flow visualization runs showed separation was consistently occurring at the locations of what seemed to be surface defects on each of the airfoil profiles. The airfoils were manually refinished to remove the surface discontinuities and reinstalled. Tests were performed at Mach number 0.7 and results show that the full span pressure losses were reduced with the refinished airfoils. The reduction in total losses decreased as the airfoil thickness increased. The trend of loss with airfoil thickness remained the same as in the original tests. Author (CISTI)

THE EFFECT OF AXIAL VELOCITY RATIO, TURBULENCE INTENSITY, INCIDENCE, AND LEADING EDGE GEOMETRY ON THE MIDSPAN PERFORMANCE OF A TURBINE CASCADE **c07**
D. R. Whitehouse, S. H. Moustapha (Pratt and Whitney Aircraft of Canada Ltd., Longueuil, Quebec.), and S. A. Sjolander (Carleton Univ., Ottawa, Ontario.) *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 21-24 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

Tests were carried out in a low-speed large-scale planar cascade test section to investigate the effect of axial velocity ratio (AVR), incidence, and turbulence intensity (TI) on the midspan performance of a turbine blade. The effect of leading edge geometry was investigated by comparing the results with those of Rodger (1992). Flow measurements were made with three-hole pressure probes mounted in planes upstream and downstream of the cascade. Measurements included midspan total pressure loss and flow performance. As the positive incidence increases, the overspeed increases, creating a strong adverse pressure gradient near the blade leading edge. Flow visualization confirmed the presence of boundary layer separation at +20 deg incidence. The strong adverse pressure gradient caused by the endplates (used to establish two-dimensional flow) appears to be the dominating influence on the boundary layer. An observed sensitivity of blade losses to AVR at high positive incidence highlights the importance of comparing loss measurements at AVR=1.0. Losses rose very quickly as AVR was reduced below 1.0. Turbulence intensity and changes in leading edge geometry had little or no effect on blade off-design losses for the AVR range studied. Author (CISTI)

EXPERIMENTAL AND THEORETICAL STUDIES OF T-TAIL CONFIGURATIONS FOR COMMUTER AIRCRAFT APPLICATIONS c05

J. B. Coll, S. W. Cosby, and A. B. Paige *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 25-28 (For primary document see N94-28315 07-02)

Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

The design of a horizontal tail leading edge for a commuter aircraft is discussed relative to the existing production standard and an experimental comparison is made between them. Three fin cap fairing definitions are shown and an assessment of their respective performance in light of wind tunnel test results is offered. Three objectives were set for the modification of the existing production standard horizontal tail section: reduction of high speed buffet due to shock waves near the leading edge; retention of the existing low speed characteristics of the airfoil section; and minimization of structural modifications to the existing aircraft layout. Analysis of the standard and modified tails was restricted to two-dimensional sections and was performed using the potential method of Bauer et al (1977) with viscous corrections and a Boeing Euler code with coupled boundary layer (Choupani and Om, 1987). The modified leading edge was shown to have similar lift characteristics to the standard leading edge but a significantly reduced buffet level. The two modified fin cap fairings produced significantly lower drag than the production standard version. The extended fore and aft fairing had an impressive reduction in buffet level at high Mach and Reynolds numbers. Author (CISTI)

MEASUREMENTS OF STEADY AND DYNAMIC PRESSURE ON AN F/A-18 WIND TUNNEL MODEL AT HIGH ANGLES OF ATTACK

F. C. Tang and B. H. K. Lee *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 29-32 (For primary document see N94-28315 07-02)

Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

A wind tunnel investigation was conducted to expand the knowledge of high angle of attack aerodynamics and the structure of vortical flows. Measurements were made in the transonic test section of a 1.5 by 1.5-m wind tunnel using a six percent scale model of a F/A-18 aircraft in the Mach number regime of 0.25 to 0.9. Pressures on the upper and lower starboard leading edge extension and wing surfaces were measured and oil dots flow visualization experiments were carried out. The surface skin friction lines show presence of wing-tip and leading-edge vortices. Three dimensional pressure distribution plots of the wing surface show low pressure regions typical of those detected in the presence of vortical flow. The results are in good correlation with those obtained from flow visualization. Spectral analyses of the wing surface pressure signals indicate that the unsteady pressures can be represented by a Gaussian distribution. The deduced wing normal force has statistical properties resembling that of a Gaussian random process. At Mach number 0.6, the wing normal force coefficient varies with angles of attack monotonically. The fluctuating normal force coefficient rises rapidly at angles of attack around 25 degrees. The increase of unsteadiness is due to the bursting of vortex ahead of the wing at higher angles of attack. Author (CISTI)

APPLICATION OF THE MBTEC EULER CODE TO THE CHALLENGER AND THE CF-18 COMPLETE AIRCRAFT CONFIGURATIONS c05

F. Kafyeke and P. Piperni *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 33-36 (For primary document see N94-28315 07-02)

Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

The Canadair Multiblock Transonic Euler Code (MBTEC) has been extended to handle the geometry of complete aircraft configurations. Application of MBTEC to the Canadair CL-601 and CF-18 aircraft configurations is illustrated. MBTEC uses a system of Euler equations written in conservative form and is discretized on a structured body-fitted grid, using a finite volume technique. The scheme employs central differencing for the spatial operators. The resulting ordinary differential equations are integrated in time using a five-stage Runge-Kutta method. Artificial viscosity is added to stabilize the scheme and various convergence acceleration techniques are used including residual averaging and enthalpy damping. The code also has modified boundary condition formulations including additional boundary conditions for turbofan inlets and exhausts. The CL-601 grids use 30-600 blocks. Results have been used to indicate the effects of the winglet and of the interference between the nacelle and the wing. The CF-18 grids use 108 blocks and results have been obtained for a cruise condition at Mach 0.95 and a high angle of incidence condition at Mach 0.6, in comparison with wind tunnel data. INFRARED IMAGING FOR TRANSITION DETECTION IN A TRANSONIC BLOWDOWN WIND TUNNEL c74

I. Fejtek, G. D. Jones, and R. Panza-Giosa *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 37-40 (For primary document see N94-28315 07-02)

Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

Detection of boundary layer transition from laminar to turbulent flow is an important capability in wind tunnel testing. Infrared imaging offers a technique for detecting such transitions that is nonintrusive, available continuously in real time, easy to use, and affordable. Experiences with this new technology are reported, with reference to wind tunnel tests of a supercritical airfoil. It is shown by a simple expression that if there is a temperature difference across a boundary layer, the heat transfer in a laminar boundary layer is low and the heat transfer in a turbulent boundary layer is high, up to ten times greater. If the flowing fluid is cooler than the model being tested, the surface temperature of that part of the model experiencing laminar flow will remain nearly unchanged while that where the flow is turbulent will drop. In the wind tunnel tests described, the thermal imaging system comprised an infrared scanner and a personal computer based system controller. High intensity infrared heat lamps were found to be the best way of heating the model surface, which was coated with thermally insulating nonreflective paint. It is seen that infrared imaging is not only useful for detecting the boundary layer transition but also for detecting large regions of separated flow. Author (CISTI)

UNIFIED APPROACH FOR DIRECT AND INVERSE BOUNDARY LAYER PREDICTION USING CUBIC SPLINE COLLOCATION c34

A. Ilinca, B. C. Basu, and J. Godin *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 41-44 (For primary document see N94-28315 07-02)

Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

A method proposed to improve the accuracy of the velocity profile together with its first and second derivatives in the normal direction for incompressible boundary layers has been extended to the compressible case. The method, which uses spline collocation in the direction normal to the wall and finite difference discretization in the direction parallel to the wall, has also been applied to inverse problems in incompressible boundary layers. The direct problem consists in predicting the velocity and temperature profiles inside the compressible boundary layer while the temperature and the velocity or pressure distribution at the edge of the boundary layer are known. An inverse problem is one in which the streamwise distribution of wall shear or displacement thickness is given, while the external pressure or velocity is unknown. The numerical procedure is presented for the incompressible case both for direct and inverse problems. The computation is performed on a structured, rectangular, nonuniform grid. Results are shown for direct computation of a compressible boundary layer and inverse computation of an incompressible boundary layer. Author (CISTI)

The SCOLIC computer code was developed for three dimensional compressible boundary layers on airfoils operating in the transonic regime. The problem of estimating the location of the laminar to turbulent transition is solved using temporal stability theory, and the point of transition is estimated according to an amplification or N-factor criterion. The methodology used in the computer code is described and some results using SCOLIC are presented. Transition predictions obtained with SCOLIC were compared to experimental data for seven different airfoils and it was found that the results were generally satisfactory. Test results for the NAE airfoil series are typically represented by the NAE-80-060. The calculated N-values suggest that the profile design is very effective at suppressing instabilities. Eventually, an instability of frequency 11,456 Hz, with point of inception at about 10 percent chord, does lead to transition around 64 percent chord which agrees remarkably well with experimental observations. For the E-580 NLF airfoil, computed results indicate that instabilities at 162 Hz and 143 Hz lead to transition at about 60 percent chord, while the transition is experimentally observed to occur at 62.6 to 65 percent chord. SCOLIC reproduces the suppression of leading edge instabilities observed with this airfoil. Author (CISTI)

EXPERIMENTAL STUDY ON THE SHOCK WAVE INTERACTION WITH A HYPERSONIC BOUNDARY LAYER NEAR A CONVEX CORNER
R. J. Hawboldt, P. A. Sullivan, and J. J. Gottlieb *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 49-52 (For primary document see N94-28315 07-02)

For many proposed scramjet engine inlet geometries, a thick boundary layer can develop on a long external compression surface before the flow is turned around a convex corner into the engine by an oblique shock wave. Separation at the corner is possible, thereby reducing the performance of the inlet. Experiments were conducted in a hypersonic gun tunnel to compare the onset and extent of separation of a laminar boundary layer caused by a shock wave impinging near a convex corner to the case of a shock reflecting from a flat plate. Some data were also provided for the validation of computational fluid dynamics codes. Surface static pressure was measured on a planar model that comprised a flat shock generator plate and an instrumented plate configured as either a flat plate or as a convex corner. The surface static pressure distribution was measured through four shock wave and flat plate boundary layer interactions and over two different convex corners. The interactions fell into three categories depending on the location of the separation and reattachment points with respect to the convex corner. The extent of flow separation is minimized when the separation point is located at the convex corner. For laminar flow, the ideal of perfect shock cancellation at the convex corner is unattainable. Computational techniques have been developed for the accurate calculation of the flow field in the wing/fuselage junction area of aircraft. Solving the Euler equations coupled with an integral boundary layer analysis for the wing/fuselage problem presents difficulties in modelling confluent boundary layers. Solution of the Navier-Stokes equations offers the potential for far greater accuracy for this type of calculation. The thin-layer approximation is made both normal to the wing and to the fuselage to compute the boundary layers. The equations are transformed into a generalized, body-fitted, curvilinear coordinate system and nondimensionalized with respect to freestream flow values. The system of equations is closed by relating the pressure to the conservative flow variables through the equation of state for a perfect gas. The numerical algorithm used to solve the three dimensional compressible thin-layer Navier-Stokes equations is an implicit, time accurate scheme called LU-ADI factorization. The computational grid is single-block and structured, with the wing and wake lying on one boundary of the computational domain. Results are presented for a preliminary solution obtained for the Dash-8 aircraft at zero angle of incidence and Mach number 0.6, showing rapid deceleration of flow ahead of the leading edge of the wing root. APPLICATION OF THE INFLUENCE FUNCTION METHOD USING THE INTERFERENCE DISTRIBUTED LOADS CODE TO PREDICTION OF STORE AERODYNAMIC LOAD DURING SEPARATION FROM THE CF-18 FIGHTER AIRCRAFT
Ahmed Malek *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 57-60 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

A hybrid numerical and experimental technique was used to predict aerodynamic loads for a series of external stores for the CF-18 aircraft. The method recognizes that every store has a unique response to the local flow angularities, both the upwash and sidewash, in the proximity of the parent aircraft. The numerical technique, based on the influence function method (IFM), requires that the store of interest be calibrated in a known nonuniform flow field and that the parent aircraft flowfield angularities are known at the store flight regimes of interest. In recognition of the costly wind tunnel test data required by the method's calibration process, a numerical tool, the Interference Distributed Loads (IDL) code, was used in conjunction with the IFM to calculate the influence coefficients of the store of interest. Upwash and sidewash distributions in the under-wing flow field of a CF-18 model were obtained from wind tunnel measurements and the IFM/IDL method was used to predict the aerodynamic loads for a particular CF-18 external store. The predictions were compared with previous calculations in which stores calibration was performed in a flow field generated by an ogive-cylinder body. The IFM/IDL method provided better prediction of store moment coefficients, while the previous method gives better prediction of the store force coefficients. Author (CISTI)

AERODYNAMIC PERFORMANCE OF NOVEL DUCTED-TIP WINGS
S. Z. Duan and S. I. Green *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 61-64 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

Experiments were conducted in a low speed wind tunnel to study the impact of a ducted-tip wing on lift/drag performance. The wing tested was a rectangular planform NACA 66-209 airfoil fitted with 92 surface pressure taps and fitted with a variety of wing tips. The first type of tip was a nearly circular section duct attached to the wing, ranging from the full chord to 65 percent of chord length. The second kind of tip was a pair of NACA 0006 short airfoils joined at both span ends, resulting in a rectangular box assembly. A simple tip extension forming a square cut wing was used for baseline performance measurements. The partial chord ducted wing tip had superior performance to all the other tip geometries, and results are presented showing lift coefficient, drag coefficient and lift/drag ratio, and pressure distribution. At modest angles of attack, the ducted tip is significantly less efficient than a conventional tip, while at angles of attack of about 8 deg or more, the ducted tip has up to 6 percent better lift/drag performance than a square cut wing tip of equal span. The main cause of this performance improvement is the greatly reduced induced drag at high lift coefficients. It is suggested that there is a significant role for the ducted tip design in both military and civilian propeller applications. Author (CISTI)

Examples are presented of recent work using classical analytical methods to model airfoil stall. Where separated flow is involved as with airfoils near stall, it is realistic to assume that the airfoil surface exposed to the wake is at constant pressure, and that the shear layers bounding the wake can be simulated by free streamlines. The airfoil pressure loading and the flow pattern outside the wake can then be determined using the powerful properties of singularities in creating the flow models and conformal mapping in solving the resulting boundary value problems. The method is first applied to single and two-element airfoils experiencing trailing edge stall. For a single airfoil, a simple series of conformal transformations is used to map a Joukowsky airfoil, with part of its upper surface removed, onto a circle for which the flow problem is solved. The simplicity of this method permits its extension to airfoil-flap configurations in which trailing edge stall occurs on the flap. The pressure distribution calculated by the theory for a single Joukowsky airfoil closely matching a NACA 23012 profile was compared to wind tunnel measurements and showed good agreement. NON-ISOENERGETIC INVISCID SLOT FLOW

D. M. Stropky, I. S. Gartshore, and M. Salcudean *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 69-72 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

A new method was developed for predicting the flow from an arbitrarily inclined slot into a uniform free stream of arbitrarily different density and total pressure. With inviscid flow, the streamline separating the injectant and main stream can be considered as a solid boundary. The flowfield is divided into two zones, an internal region containing the slot fluid and an external region composed of the free stream fluid. Each region is solved independently, while the dividing streamline shape that provides continuity of static pressure is determined via an iterative procedure. Selected results are presented, showing that inviscid theory, when carefully applied, can describe the essential features of the flow provided some allowance is made for separation from the downstream lip at higher mass flow ratios and higher slot angles, and provided that the mainstream boundary layer is thin relative to the slot width. For application to secondary injection devices such as film-cooled turbine blades, the method shows that diffusive effects in most cases are not important for predicting the mass flow ratio.

CALCULATION OF UNSTEADY INCOMPRESSIBLE INVISCID FLOW ABOUT WINGS AND BODIES USING CANAERO-T PANEL MODEL

F. I. Tezok and J. T. Conway (Agder Coll. of Engineering, Gromstad, Norway.) *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 73-77 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

CANAERO-T is a low order, time-stepping panel method modeling the unsteady potential flow around a configuration using linear source panels on the surface and bi-linearly varying doublet panel distribution along the span and camber surface. The implementation and testing of the CANAERO-T unsteady code is described, along with a description of the mathematical formulation of the method, some features of which appear to be unique. Results and discussions are presented for the case of an impulsively started wing, an impulsively started oscillating wing, and a submarine performing a slow oscillation of drift angle. Pressure distributions and wake structures calculated for the wings are illustrated. The oscillating wing solution clearly shows an oscillatory shape of the wake and a wake self interaction causing a mushrooming effect in the wake geometry downstream. Author (CISTI)

DRAG PREDICTION BY WAKE INTEGRALS USING 3-D MULTI-GRID EULER METHOD (MGAERO)

G. C. Waller *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 78-81 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

A method of drag prediction for Euler methods by integration of flow properties across the model wake developed by van Dam was applied to the MGAERO three dimensional multi-grid program used in aircraft aerodynamic design. Van Dam derived integral expressions for lift and drag based on the equations of motion for steady, inviscid three dimensional flow about a lifting wing. In MGAERO, the van Dam method is applied by placing a survey plane normal to freestream downstream of the model, and the cross-flow velocity components are calculated over a rectangular mesh. The derivative of the velocities gives local vorticity, which in turn is integrated to give local stream function. These variables give the lift and induced drag terms; wave drag is derived from the integral of entropy over the survey plane. The MGAERO wave drag estimate value compares sensibly with van Dam's estimates for a NACA-0012 airfoil, and the MGAERO wake integral drag value is greatly improved over the surface pressure integration value. In applying wake integral drag estimation to the design of a high-wing turboprop configuration, good agreement in lift curve and induced drag was obtained with a vortex lattice panel program. The MGAERO program represents a more detailed model of the aircraft and its flowfield, so that more subtle design changes can be evaluated against drag.

A NEW APPROACH TO TURBOPROP FORWARD NACELLE DESIGN
c07

I. Adare, I. Fejtek (De Havilland Aircraft Co. of Canada Ltd., Downsview, Ontario.), S. Bedi, and J. Coll (De Havilland Aircraft Co. of Canada Ltd., Downsview, Ontario.) *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 82-85 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

An innovative nacelle design capability was developed that significantly reduces the time for turboprop forward nacelle design and simplifies the effort required to generate nacelle shapes. The approach is an extension of the surface modeling methodologies developed by Bedi et al, in which the forward nacelle is viewed as being a blended surface joining, at the front end, a circular shape representing the spinner opening and another elongated shape representing the inlet opening, and at the aft end, a near-rectangular shape. By providing control over the manner in which the blending is performed, a variety of nacelle shapes can be generated which are smooth and which meet various geometric constraints imposed by engine and gearbox locations. The blending technique used in the modeling is based on the Bernstein basis functions. Once the surface is created using the above blending method, it is automatically divided into a network of quadrilateral panels. The output is in a surface panel format suitable for input to the aerodynamics computer program VSAERO. The interactive computer algebra package MAPLE is an integral part of the method. The entire design process comprising nacelle surface blending, surface grid generation, and VSAERO analysis can take under an hour of elapsed time on a workstation. Further refinements of the method are planned.

A solution adaptive grid generator can reduce the numerical errors in fluid flow computations by clustering grid points in regions of high error. A study of adaptive redistribution applied to viscous airfoil flows is presented

which uses the adaptive method of Eiseman. An elliptic system of partial differential equations is formulated with control functions which adaptively cluster points to specified regions in each coordinate direction. The adaptive grid generation scheme is applied to C-grid configurations about airfoil sections. Results are presented for unadapted hypberbolic and elliptic grids as well as for adapted elliptic grids. Parametric studies were conducted to determine a suitable set of input parameters for both boundary layer and streamwise pressure adaptation. Several forms of the weight function were investigated and it was found that a Mach number gradient formulation with a clustering parameter dependent on the grid geometry gives good results. The results show that grid adaptation effectively reduces the lift and overall drag errors for all cases and all grids studied. The magnitude of the error reduction depends on both the flow characteristics and the initial grid. In particular, errors in friction drag are substantially reduced.

SOLUTION OF THE EULER EQUATIONS USING UNSTRUCTURED GRIDS

D. J. Jones and B. MacLeod *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 90-93 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

Unstructured grids have many advantages over structured grids in solving computational problems of aerodynamic interest. A technique for generating unstructured grids has been developed, based on Voronoi regions and Delaunay triangulation, which can produce grids with nearly equilateral triangles in two dimensions. In an application of the technique, the Delaunay grid was obtained and then the method of Stolcis and Johnston (1990), based largely on Jameson's method, was used to obtain solutions to the Euler equations. Emphasis was first placed on supersonic flow situations including a rare application to symmetric blunt body flows. The development was recently extended to subsonic free stream situations for airfoils as part of a validation exercise. Results from four cases are illustrated: flow around a cylinder at Mach 3, Mach 1.2 flow around a NACA 0012 airfoil at 7 deg angle of attack, flow around a sphere at Mach 1.08, and Mach 0.75 flow around a RAE2822 airfoil at 3 deg angle of attack.

ATTACHED AND SEPARATED TRAILING EDGE FLOW MEASUREMENTS WITH A TRIPLE-SPLIT HOT-FILM PROBE

M. D. Doiron, D. W. Zingg, and P. Godin *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 94-97 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

Attached and separated trailing-edge flow measurements with a triple-split hot-film probe are presented. The probe, consisting of three nickel films deposited on a quartz cylinder and operating on the basis of variations in local convective heat transfer coefficient, has the potential to provide inexpensive measurements of separated flows. Measurements of mean-flow and turbulent stresses near the trailing edge of a 17 percent thick airfoil with moderate aft-loading were obtained at zero and 9.2 deg angles of attack at a Mach number of 0.15. Computations were also performed using the Baldwin-Lomax algebraic model and the Baldwin-Barth one-equation model (1990). Computed and measured force and moment coefficients, surface pressure distributions, and mean velocity and turbulent shear stress profiles are compared. The computations show reasonable agreement with the experimental measurements for the attached flow case but differ substantially when the flow is separated. Author (CISTI)

A STUDY OF BLUNT TRAILING EDGE AIRFOILS USING THE NAVIER STOKES CODE: ARC2D

M. Khalid and D. J. Jones *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 98-101 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

The performance of a number of turbulence models is compared in terms of their ability to predict viscous flow in the boundary layer and near-wake region of airfoil profiles with blunt trailing edges. The Baldwin-Lomax model (1978) uses different expressions for tubulent viscosity in the inner and outer viscous region, with a blending formula in the overlap region. This approach was also adapted in the current Johnson-King model (1985), which relates the nonequilibrium eddy viscosity to the maximum shear stress distribution in the chordwise direction, which in turn is obtained from the kinetic energy equation. The other two models evaluated were the Baldwin-Barth and the mixing length models. For velocity profiles, the Johnson-King model provided the closest approximation to experimental data. The computations, and to some extent the velocity profile measurements, demonstrated the existence of a complex vortical flow system behind the trailing edge of an airfoil. This system influences the flow field in a global sense and has some bearing on airfoil aerodynamic performance. Author (CISTI)

THIN-LAYER NAVIER-STOKES COMPUTATIONS FOR MULTI-ELEMENT AIRFOILS

A. R. Wilkinson, T. E. Nelson, D. W. Zingg, and G. W. Johnston *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 102-105 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

Recent work on grid generation and Navier-Stokes computations for multi-element airfoils is presented. Decomposition of the flow domain into topologically rectangular blocks is accomplished using an automated procedure. The compressible thin-layer Navier-Stokes equations are solved using the diagonal form of the implicit approximate factorization algorithm of Beam and Warming (1986) extended for multiblock grids. Turbulence is modelled using the one-equation model of Baldwin and Barth (1990). The accuracy of the flow solver was investigated by detailed comparisons with experiment for several high-lift geometries with varying amounts of separation. Accurate results are generally obtained for attached and mildly separated flows. When the region of separated flow is larger, its thickness tends to be underestimated, and as a consequence, maximum lift and post-stall behavior are not predicted accurately. Although the turbulence model is a major source of error, other sources of error such as the thin-layer approximation and the treatment of the turbulent normal stresses cannot be ignored. TECHNIQUES FOR ACCURATELY SOLVING UNSTEADY SHOCK WAVES AND CONTACT DISCONTINUITIES **c34**

M. Paraschivoiu, J. Y. Trepanier, and R. Camarero *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 106-109 (For primary document see N94-28315 07-02)
Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

The upwind difference scheme of Roe (1986) is able to solve discontinuities exactly when a grid line is oriented and located along the discontinuity. Based on this property, a technique is suggested for managing the grid in order to exactly capture the shock waves and contact discontinuities appearing in inviscid, incompressible, unsteady flows. The shock wave discontinuities are first located. The neighboring mesh is then moved on the shocks for steady cases and with the shock for unsteady discontinuities. The movement takes into account the actual direction in which information is propagated. The solver used was developed by Trepanier et al (1991) and is based on a finite volume methodology applied to the solution of two-dimensional Euler equations on a general moving grid with moving boundaries. The mass, momentum, and energy flux are evaluated by solving an approximated Riemann problem. In the algorithms for grid management, triangulation is optimized so that cell boundaries are set normal to wave motion and each element is moved so that the shock itself forms part of the mesh line. The algorithms are tested for shock tube flow, oblique shock reflection, and parallel streams. Grid management was able to refine and coarse the grid until the discontinuity is captured exactly. A NEW FLUX VECTOR SPLITTING SCHEME c34

G.-C. Zha and E. Bilgen *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 110-113 (For primary document see N94-28315 07-02)

Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

A new flux vector splitting scheme is suggested which uses the velocity component normal to the volume interface as the characteristic speed and yields the vanishing individual mass flux at the stagnation, which may achieve accuracy for viscous flows. The scheme is very simple and easy to implement. The scheme has been applied to solve the one-dimensional and multi-dimensional Euler equations for shock tube flow. The solutions are monotone, and the normal shock wave profiles are crisp. For a one-dimensional shock tube problem with shock and contact discontinuities, the present scheme and Roe's flux difference splitting scheme give the best results compared to those from Van Leer's flux vector splitting scheme (1991) and Liou-Steffen's AUSM scheme (1991). For multi-dimensional transonic flows, sharp monotone normal shock wave profiles with mostly one transition zone are obtained. The results agree well with those from Van Leer's scheme and the AUSM scheme. Author (CISTI)

SOLUTION-ADAPTIVE SIMULATION OF TRANSONIC CASCADE FLOWS

T. C. Currie *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 114-117 (For primary document see N94-28315 07-02)

Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

A solution adaptive, two-dimensional code has been developed to solve the Euler or Navier-Stokes equations on triangular grids. The Euler fluxes of mass, momentum, and energy are integrated over the faces of non-overlapping polygonal cells formed from the median dual of a triangular mesh. Interfacial fluxes are evaluated using Roe's flux difference splitting scheme (1981). A Galerkin discretization of the viscous terms is used, assuming piecewise linear variation of the primitive variables within the triangular cells. The discretized equations are solved with either a multigrid accelerated Runge-Kutta time-marching scheme or a fully implicit Newton-Raphson procedure. The multigrid algorithm is a particularly simple one adapted from a scheme originally developed by Denton (1984) and later by Wang et. al. (1991) for structured grids. The code described has been validated against several benchmarks including inviscid flow in a supersonic compressor cascade and laminar flow over a flat plate. Author (CISTI)

ICE ACCRETION ON AIRCRAFT WINGS c03

P. Tran, M. T. Brahimi, and I. Paraschivoiu *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 118-121 (For primary document see N94-28315 07-02)

Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

A three dimensional inviscid code for ice accretion on wings (Tran et al, 1992) was modified to account for viscous effects by matching the flow field to solutions obtained with a boundary layer calculation code. The flow field calculation uses a viscous inviscid interaction technique involving a panel method based on the integral singularity method, a boundary layer correction, and a suitable matching procedure using the transpiration velocity model. The numerical solution for analyzing the ice accretion consists in computing the flow characteristics around the wing and then calculating the impingement of droplets on the wing. The laminar boundary layer calculation is based on the method of Thwaites (1960) and the transition to turbulent flow is calculated using Michel's (1951) criterion. Droplet trajectories are calculated by assuming that the volume and density of the droplet remain constant and the initial droplet velocity equals the freestream velocity. The velocity field is used to compute the trajectory of a given droplet to determine whether it impinges on the wing. The droplet impact point calculation is two-dime nsional. Comparison of ice accretion obtained with INTERICE for a NACA 0012 airfoil are presented, showing good agreement with experimental results. The importance of viscous effects near the leading edge is noted. Author (CISTI)

PRELIMINARY ASSESSMENT OF AERODYNAMIC EFFECTS OF WING REPAIR PATCHES

R. J. Kind and C. Carnegie *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 122-125 (For primary document see N94-28315 07-02)

Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

A preliminary assessment was obtained of the possible negative effects of aircraft damage repair patches on the aerodynamic performance of a CF-18 aircraft wing. Wind tunnel tests were conducted to measure the effects of patches of various thickness on two-dimensional boundary layers. The wind tunnel data were used to develop a set of correlation curves for describing the main effects of patches on boundary layers. These correlations are incorporated into computations for analysis of two-dimensional viscous incompressible flow, including stall effects, over airfoils. An inviscid potential flow (panel method) program is coupled with a boundary layer program into which the correlations are incorporated. Boundary layer displacement and separation effects modify the potential flow solution, and the predicted drag and lift on the airfoil. The results suggest that half-inch thick patches on a CF-18 wing would cause large reductions in lift at angles of attack near that for section stall, but that only moderate lift reductions would occur at lower angles of attack, provided that most of the pressure recovery aft of the suction peak has occurred before the flow reaches the patch. Patches cause substantial drag increases at all angles of attack below stall. Author (CISTI)

A method for predicting unsteady, three dimensional compressible flows governed by the Euler system of equations is presented. The approach uses the Euler-Lagrange formulation, a finite volume scheme based on Roe's approximate Riemann solver (1981) and unstructured moving grids. To achieve flexibility in the aspects related to the geometric representation as well as grid management, tetrahedra have been used as the elementary discretization cells. An algorithm for the management and coupling of moving tetrahedra with the flow solver has been devised. The method has been tested on static and moving meshes and the results show the correct behavior of different flow fields. Some preliminary results for simple geometries are presented. These address the oblique shock wave in the flow past a dihedron, flow in a three dimensional channel, and flow inside a cube with a moving face. Author (CISTI)

The spectral element method is used for direct simulation of incompressible fluid flow in two and three dimensions. The full unsteady viscous Navier-Stokes equations are solved. To increase this method's flexibility in handling complex geometry flows found in real engineering problems, an adaptive grid generation method is being developed. Once a grid is constructed and the solution to the Navier-Stokes equations has started, the grid can be adapted as the flow develops in time to optimally reallocate resolutions to regions of flow where it is most needed. Further increase in flexibility can be achieved by loosening restrictions on the elements to be used. Certain aspects of the adaptive grid generation method and formulation using triangular elements are discussed. Components of the grid system are illustrated with a one-dimensional solution to the Burgers equation, a good model for the Navier-Stokes equation. Triangular elements have been developed which employ fast tensor products to calculate elemental residuals. The success of the triangular element implementation is illustrated by a convergence plot for the solution of Poisson's equation on a two triangle grid with Dirichlet boundary conditions. The Poisson equation serves as the kernel of the Navier-Stokes solver. Author (CISTI)

MULTIGRID SOLUTIONS OF THE 2D EULER/NAVIER-STOKES EQUATIONS ON UNSTRUCTURED MESHES **c34**

Farzad Mokhtarian *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 134-135 (For primary document see N94-28315 07-02)

In solutions of the two-dimensional Euler Navier-Stokes equations on unstructured triangular meshes, discretization of the governing equations is achieved using a finite element Galerkin approximation. Integration to steady state is performed using a multistage time stepping scheme, and convergence is accelerated using implicit residual smoothing and an unstructured multigrid algorithm. An algebraic turbulence model based on the Baldwin-Lomax model is implemented, based on the use of local background structured turbulence meshes. The local structured meshes are constructed using a hyperbolic mesh generator, which uses the boundary point distribution of the unstructured mesh as its initial condition. The local structured turbulence meshes are triangulated to carry out the interpolation procedure required for the execution of the turbulence model. The code is validated by comparing turbulent flow solutions about RAE2822 and NACA0012 airfoils with experimental data. The efficiency of the code is also evaluated with regard to calculations in Euler as well as both laminar and turbulent Navier-Stokes modes, with special attention to the grid and thus, to the processing requirements of the code. A wind tunnel was used to investigate the aerodynamic characteristics of a supercritical airfoil section. Tests were conducted in two different sized test sections. Comparisons of results from the two test sections are used to show the effects of the sidewall boundary layer. The investigations supported the present method of making the Mach number and incidence corrections for the ceiling/floor wall interference effects based on the classical concept of representing the model with a system of vortex, doublet, and source. The influence of the sidewall boundary layer effects result in not only a decrease in local freestream Mach number but also in an inducement of a spanwise Mach number gradient, which affects the spanwise distribution of the airfoil aerodynamic characteristics. Investigations on short-span models in the smaller of the two test sections show that the sidewall boundary layer effect in disturbing the two dimensionality of the test section flow leads to a spanwise nonuniformity of the drag distribution, especially near the flow conditions for the airfoil drag divergence where the drag levels are sensitive to even small Mach number differences across the span. Progress is reported in the numerical modeling of wind tunnel sidewall interference using the ARC3D code. This code was originally configured to compute flows through a duct containing a center body, and was altered to compute flows about wings of constant cross section. ARC3D solves the Euler equations or the thin-layer Navier-Stokes equations transformed into the numerical cordinate system and converted into a conservative second order accurate central difference equation for flow evolution at each internal cell vertex. The residual at each internal cell vertex is updated by adding the fluxes through the walls of an equivalent cell surrounding each internal cell vertex. Second- and fourth-order artificial dissipation terms are added to the fluxes to prevent instability of the solution. The system of equations is iterated towards the steady state using an implicit approximate factorization time-stepping algorithm. Pressure profiles across the airfoils obtained using preliminary ARC3D calculations are illustrated. Various methods used to eliminate pressure spikes generated by the code are discussed. EVALUATION OF THE BUOYANCY DRAG ON AUTOMOBILE MODELS IN LOW SPEED WIND TUNNELS **c34**

Miroslav Mokry *In* Canadian Aeronautics and Space Inst., Abstracts of Papers Presented at the 4th CASI Aerodynamics Symposium 1993 p 144-147 (For primary document see N94-28315 07-02)

Avail: Issuing Activity (Canadian Aeronautics and Space Inst., 130 Slater Street, Suite 818, Ottawa, ON K1P 6E2 Canada)

Of the several sources of inaccuracy in interpreting wind tunnel data for automobile models, the most prominent is the blockage interference. Streamwise variation of the wall induced pressure gives, in addition, rise to buoyancy drag. Buoyancy drag is analyzed in closed, 3/4 open, and slotted wind tunnels. The disturbance velocity potential is represented by a simple layer distribution. A numerical solution is obtained by a first-order panel method, approximating the surface by an assembly of flat panels, with a piecewise constant source density. The increment of the pressure coefficient due to wall interference considers only the contributions of the wall panels. Examples of the calculated buoyancy drag are given for the generic car model of the Motor Industry Research Association. Judged by the magnitude of the buoyancy drag, experiments at high blockage ratios would be highly distorted if performed in a closed-wall test section. However, with 30 percent open area ratio slotted walls, the buoyancy drag is reduced to about the same magnitude as that for test sections with low blockage ratios. Author (CISTI)

A FEASIBILITY STUDY ON BIRD CLASSIFICATION WITH NEURAL NETWORK Final Report
P. P. Meiler Jun. 1992 61 p
(AD-A273753; FEL-91-A301; TDCK-TD-91-4352) Avail: CASI HC A04/MF A01

This study shows that it is feasible to classify flying birds using radar and neural network technology. The Royal Dutch Airforce is interested in the capability to classify birds because this capability can be used to avoid collisions between birds and airplanes. The Automatic Gain Control (AGC) signal which is generated by the Flycatcher tracking radar has a relationship with the wing stroke pattern of a bird. An automatic system to classify birds using the AGC signal could be used in a bird collision warning system. Such a system does not yet exist. A prototype of a bird classification system has been implemented and evaluated. Test results based on simulated AGC data show that the prototype is able to classify birds. The prototype uses simulated AGC data because there is not yet enough real AGC data available to use neural network technology. Acquisition of real AGC data is too expensive to be done in the framework of a feasibility study. According to the test results it is recommended to acquire real AGC data. DTIC

A system is disclosed for generating an alarm signal on an aircraft in case of takeoff malfunctions. According to the invention, means are provided for delivering signals representative of the theoretical and real accelerations of the aircraft, at a given instant. Other means are provided for calculating the predicted real distance travelled by the aircraft at a theoretical aircraft velocity corresponding to the real aircraft velocity, and for calculating the ratio of the above calculated distance to the theoretical distance travelled by the aircraft. The above ratio is compared to a predetermined level guaranteeing a minimum safe distance for braking and stopping the aircraft. An information signal is supplied to alarm means which are capable of emitting an alarm signal if the above ratio is greater than or equal to the predetermined level. According to another characteristic of the invention, the system includes means for determining the variation in the longitudinal component of the wind and for providing alarm signals when this variation is greater than or equal to a predetermined level. IMPACT OF IMPROVED MATERIALS AND CABIN WATER SPRAY ON COMMUTER AIRCRAFT POSTCRASH FIRE SURVIVABILITY
Timothy R. Marker Nov. 1993 35 p
(AD-A274421; DOT/FAA/CT-TN93/40) Avail: CASI HC A03/MF A01

Twelve full-scale tests were conducted in a modified Metro-liner fuselage to study the impact of using improved fire retardant materials and a cabin water spray system on postcrash fire survivability. Currently, commuter category aircraft as defined in Part 23 are exempt from meeting the stringent Federal Aviation Regulations (FAR's) requiring seat cushion fire blocking layers and low heat/smoke release panels in large transport aircraft. A zoned cabin water spray system which allowed for the individual activation of spray zones depending on cabin temperature was designed and installed in the fuselage. The system consisted of four 100 inch long zones, each containing 6 nozzles. Of the twelve tests, five were run with the water spray system and a different combination of cabin materials. These five tests were repeated without the water spray system in order to establish baseline data for each material combination. Two additional tests were conducted to investigate the impact of a partially obstructed forward test and also to evaluate the effect that the channel-type floor geometry used in the Metro-liner aircraft has on flame propagation during a cabin fire. Temperature, smoke levels, and gas concentrations were continuously monitored at a forward cabin location and each test was recorded on video. DTIC

METHODOLOGY DEVELOPMENT OF FORECASTING INTER-REGIONAL AIR TRANSPORT DEMAND IN CHINA [ENTWICKLUNG VON PROGNOSEMETHODEN FUER DIE INTERREGIONALE LUFTVERKEHRSNACHFRAGE IN CHINA]
Ming Zhang (Chinese Aeronautical Establishment, Beijing.), Mingming Feng (Chinese Aeronautical Establishment, Beijing.), Hans-Gustav Nuesser, and Dieter Wilken Jul. 1993 84 p
(ISSN 0939-2963)
(DLR-FB-93-24; ETN-94-95500) Avail: CASI HC A05/MF A01

The selection and calibration of three types of mode specific models to be used to forecast air transport demand in China are described. These mode specific models are the growth factor method, a direct demand travel flow, and a trip generation model. For a forecast application with data available in China, a combined flow and trip generation model is recommended, which was calibrated on the basis of cross sectional data as well as time series data. For improving the forecast method, it is suggested to collect multimodal data of travel flows in the domestic air transport network of China. ESA

SPECIAL INVESTIGATION REPORT: SAFETY ISSUES RELATED TO WAKE VORTEX ENCOUNTERS DURING VISUAL APPROACH TO LANDING
Feb. 1994 98 p
(PB94-917002; NTSB/SIR-94/01; Rept-6264) Avail: CASI HC A05/MF A02

Since December 1992, there have been five accidents and incidents in which an airplane on approach to landing encountered the wake vortex of a preceding Boeing 767 (B-767). Thirteen occupants died in two of the accidents. The encounters, which occurred during visual conditions, were severe enough to create an unrecoverable loss of control for a Cessna Citation, a Cessna 182, and an Israel Aircraft Industries Westwind. Additionally, there were significant but recoverable losses of control for a McDonnell Douglas MD-88 and a B-737 (both required immediate and aggressive flight control deflections by their flight crews). Safety Board data show that between 1983 and 1993, there were at least 61 accidents and incidents in the United States, including the 5 mentioned above, that resulted from probable encounters with wake vortices. In these 61 encounters, 27 occupants were killed, 8 were seriously injured, and 40 airplanes were substantially damaged or destroyed. The Safety Board conducted a special investigation to examine in detail the circumstances surrounding the five recent accidents and incidents to determine what improvements may be needed in existing procedures to reduce the likelihood of wake vortex encounters. The Safety Board's investigation initially focused on why the B-757 appeared to be involved in a disproportionate number of wake vortex encounters. Several reports indicated that the B-757 generated wake vortices that were more severe than would be expected for an airplane of its weight. However, as a result of a thorough study and analysis of the issue, the Safety Board found little technical evidence to support the notion that the wake vortex of a B-757 is significantly stronger than indicated by its weight. The new competition conditions in air business, due to the single European market, are examined. The Brussels commission proposed a liberalization law, which guarantees price freedom and allows any service to be offered by any airline in any country of the European community; former capacity restrictions were suppressed. Freight and charter activities were submitted to the same conditions. In order to avoid the excesses of American deregulation, which causes a concentration of traffic on big, dominating companies, a liberalization through elimination of unnecessary rules was desired by European bureaucracy. The future development of air traffic is found to be currently restricted by the lack of runway capacity in European airports. Prices are assumed to be increased since the government aids are suppressed. The problem of airline mergers and cooperations, which could cause the overwhelming supremacy of United Airlines, British Airways and Japan Airlines, was examined. ESA

The consequences of deregulation in the U.S. are reviewed and their transposition to the European case are examined. After fifteen years of deregulation three airlines are dominating the commercial aviation market and the other ones are facing overcapacity problems. Oil crisis, economic recession, and deregulation of the American financial system from 1984 to 1990 played an important role in the sluggishness of the current aviation market. Some advantages were offered to the consumer by deregulation: price drop, increased choice of proposed flights such as regional lines and development of a so called social tourism, enhanced by low prices. On the other hand, some point to point connections disappeared so that passengers had to be in transit in overcrowded hubs and service quality dropped. If a similar liberalization occurs in Europe the influence of national administrations might avoid such excesses and allow profitability and travel easiness to be combined. ESA

The European air transportation market is examined considering the changes due to the single European market and the political and economical evolutions in Eastern Europe. For EFTA (European Free Trade Association) countries (Finland, Iceland, Norway, Austria, Sweden, and Switzerland) a solution was found: the treaty on European economic space applies the liberalization rules to the EFTA countries which asked for European Community membership. As regards countries from Eastern Europe, bilateral agreements currently exist between individual states; with the countries from the former Soviet Union, the situation is even more confused. It is noticed that, in the case of integration of Eastern Europe states in the European Community, flight safety and infrastructure problems make a differentiated utilization of liberalization measures necessary. The necessary integration of European flight safety is examined in the framework of the single European market. Members of ECAC (European Civil Aviation Conference) decided in 1990 to develop the four phases EATCHIP (European Air Traffic Control Harmonization and Integration Program) and to buy and operate the needed equipments for harmonization measures. First phase of EATCHIP will allow air space to be structured and some new routes to be opened. The second phase will supply a detailed planning of middle term harmonization; third phase will be devoted to the structure of a European radar system; with the fourth phase an improved onboard/ground communication system will be introduced. EATMS (European Air Traffic Management System) was developed in cooperation with ICAO (International Civil Aviation Organization), European Community Commission and European industry. APATSI (Airport/Air Traffic System Interface) was created for determining requirements and equipments for a new airport management strategy. A central flow management unit will allow a modern data base to be available. It is concluded that a European, well organized flight security system allows air traffic to be increased by 80%. ESA

The impact on the environment of air traffic increase due to the single European market is addressed and the chances of the European Community for a successful protection of environment are evaluated. The evolution of the European environmental policy was explained, since the 1972 Paris summit, where chiefs of states and governments decided to work for a better quality of life, until the creation of European Environment Agency and the writing of the single European act, which outlines the responsibility of member states in environment protection. Environmental damages due to air traffic were recalled: aircraft noise, harmful emissions such as carbon, sulfur and nitrogen oxides, waste treatment and ground water protection. Current activities for international standardization of aircraft nuisances are reported: the Committee on Aviation Environmental Protection of ICAO (International Civil Aviation Organization), the abatement of nuisances caused by air transport group of ECAC (European Civil Aviation Conference) decided the nitrogen oxide emissions have to be dropped from 40%; the European Commission edited a green book titled 'A common strategy for a sustainable mobility'. Copyright Avail: CASI HC A02/MF A03

The relationships between air traffic and industry in Germany are studied. It is noted that good air transportation capabilities are necessary for the installation of foreign companies in German cities and that Germany is the biggest air traffic market in Europe. Considering the expected increase in air traffic, airport capacities and infrastructures and air space control are shown to be insufficient and ineffective, and the need for political measures and important investments is ascertained. The high level of financial charges weighing on German companies is shown to be an important disadvantage regarding competitiveness, nevertheless high wages are the condition for social and political stability and high productivity, which are symbols of German quality. It is concluded that the harmonization process due to the single European market, which is a necessary condition for fair economical competition, will enhance the advantages of Germany as a geographic node and a door towards Eastern Europe. ESA

LUFTHANSA FACING THE SINGLE EUROPEAN MARKET [LUFTHANSA VOR DEM BINNENMARKT]
Axel C. Pfeil *In its* Lufthansa Yearbook 1992 Oct. 1992 p 90-104 In GERMAN (For primary document see N94-28230 07-03)
Copyright Avail: CASI HC A03/MF A03

Lufthansa's situation in the context of a single European market and the changes in the global air transportation industry is described. Lufthansa must compete with European airlines, American carriers, and Asiatic air companies whose cost structures are extremely favorable. Business and private travelers have become more and more sensitive to prices, customer faithfulness is disappearing, infrastructure capacities are too limited and expensive, and high speed trains are gaining market shares. The growth strategy of Lufthansa is based on the following: its well known strength; strategic alliances with Scandinavian Airlines, Swissair, and Austrian Airlines; and selective participation in key markets. The introduction of a profit center organization and the splitting of the global company into more flexible structures are assumed to make Lufthansa a competitive airline. ESA

Joint Aviation Authorities in the framework of the single European market and based on the recommendations of ICAO (International Civil Aviation Organization) are presented. Twelve joint aviation regulations were edited in 1992. The regulations address definitions, technical rules, turbofans, propfans, auxiliary power turbines, maintenance and time since overall, sailplanes, and all weather operations. ECAC (European Civil Aviation Conference) was in charge of air transportation personnel; the member states must accept the qualification of any pilot from another member state. Nevertheless training rules were compared in all states and discrepancies found could lead to pilot technical and theoretical testing. A common training program for pilots was written. The program will be mandatory for flight crew licensing. ESA

MUNICH AIRPORT: THE NEW LUFTHANSA HUB [FLUGHAFEN MUENCHEN: DIE NEUE LUFTHANSA-DREHSCHEIBE]
Horst Waehner *In its* Lufthansa Yearbook 1992 Oct. 1992 p 112-121 In GERMAN (For primary document see N94-28230 07-03)
Copyright Avail: CASI HC A02/MF A03

The new Munich airport (Germany), which is regarded as an example of functionality and successful integration in the landscape, is described. The airport offers to passengers central check-in in the main building with suburban railway connection and decentral checking in the four areas of the terminal. A personal transport system was developed for comfortable connections. Lufthansa was involved in the airport planning and supplied its knowhow for fashioning passenger areas. Daily, nonstop flights to 47 European cities and to New York, Miami, and Tokyo are proposed. Three hall modules compose a functional entity for import, export, and transit freight with a payload capacity of 250,000 tons. A new maintenance hall was built. Forty-three aircraft can be checked out each day. It can be concluded that Munich airport is user friendly, environmentally safe, and technically advanced. ESA

AIR TRAFFIC IN RECESSION [LUFTVERKEHR IN DER REZESSION]
Erich Meier *In its* Lufthansa Yearbook 1992 Oct. 1992 p 122-129 In GERMAN (For primary document see N94-28230 07-03)
Copyright Avail: CASI HC A02/MF A03

The air transportation market is analyzed in the framework of the current economic crisis. It is noticed that recession hurt air traffic in 1974/1975 and from 1980 to 1982; nevertheless the current situation seems to be the most difficult in the history of air transportation. It is recalled that signs of economic recession were visible before the Gulf War, but airlines were too optimistic in considering the eight previous years of prosperity. Air transportation is shown to be an early indicator of crisis; however, most airlines were not prepared for the recession and consistently overestimated the necessary capacity. The most recent studies conclude that the current crisis is only an episodic phenomenon. An annual growth rate of world air traffic of 5.5 percent is predicted until the year 2000. ESA

Copyright Avail: CASI HC A02/MF A03

The consequences of the arrival of numerous American airlines on the North Atlantic market are examined. The equilibrium in European/American air transportation is found to be disturbed; American companies can build hubs with their shuttle flights in Europe while Europeans do not have equivalent opportunities in the U.S. After the German reunification, Lufthansa thinks that the validity area of 1978 traffic agreement must be extended. Price war caused high losses and some airlines were suspected of dumping and 'predatory pricing'. ESA

A340 TESTING [AIRBUS A340 IM TEST]
Udo Guenzel *In its* Lufthansa Yearbook 1992 Oct. 1992 p 136-141 In GERMAN (For primary document see N94-28230 07-03)
Copyright Avail: CASI HC A02/MF A03

The quadrijet, long range A340 aircraft is described. After the first testing flights, reliability, security, aerodynamic quality, and starting power are proved to be totally satisfying, and landing powers are even surpassed. The 2000 flight test hours were planned so that Joint Aviations Authorities simultaneously give airworthiness certificate to both versions of the aircraft, A340-200 and A340-300. Test aircraft were equipped with a telemetry facility for direct online data transfer from test flight operations to a special control center, which could supply information to the test crew. Turbofan thrust was measured at several flight altitudes; external and internal noise and aircraft stability were evaluated. The fly by wire technology was particularly examined, in order for aerodynamic controls, flaps and redundancy systems to be tested. The CFM56 turbofan is depicted as an environmentally safe, low consumption and low noise gas turbine engine. ESA

FIRST CANADAIR JET FLIES FOR LUFTHANSA CITY LINE [ERSTER CANADAIR JET FLIEGT FUER LUFTHANSA CITYLINE]
Klaus Mueller *In its* Lufthansa Yearbook 1992 Oct. 1992 p 142-145 In GERMAN (For primary document see N94-28230 07-03)
Copyright Avail: CASI HC A01/MF A03

The new Canadair jet, which is a 50 seat, short range aircraft, derived from the Challenger CL-601 business travel aircraft, is described. The aircraft was developed for takeoff and landing on small airports without modern runways. It is equipped with two General Electric CF34-3A1 turbofan engines with thrust inverters, which are environmentally safe: low fuel consumption, nitrogen oxide emissions and noise levels. Hot air is used for deicing of lift wings and turbine inlets. The cockpit is equipped with headup guidance system, electronic flight information system, EICAS (Engine Indication and Crew Alerting System), and dual flight management system. The Canadair Jet is the first aircraft of its category to be certificated for all weather operations and is equipped with collision and shear wind warning systems. ESA

INTEGRATORS: A CHALLENGE FOR AIR CARGO [INTEGRATORS: HERAUSFORDERUNG FUER DIE LUFTFRACHT]
Erwin Maruhn *In its* Lufthansa Yearbook 1992 Oct. 1992 p 146-152 In GERMAN (For primary document see N94-28230 07-03)
Copyright Avail: CASI HC A02/MF A03

Activities of integrators, which have deeply modified the freight market, whose annual growth is predicted to be of 6.5% until the year 2000, are described. New logistics and distribution concepts allowed a large development of just in time delivery; integrators appeared in the U.S. after the air cargo deregulation act in 1977. Their advantages are quickness, reliability and service quality, enhanced by a uniform organization, use of modern telecommunication technologies and sending handling, based on the hub and spoke system, in a harmonized network. In order to react to this concurrence, Lufthansa created a 'collect and deliver' company, which supplies house to house carriage with combined ground and air transportation, and cooperates in Traxon, a global information system, with other companies involved in air cargo, such as Air France, Japan Airlines and Cathay Pacific. In 1990, Lufthansa took a financial stake in DHL integrator. It is concluded that only customers can jeopardize the place of the integrators on freight market. ESA

POWERFUL SELLING AND SALES STRATEGY [SCHLAGKRAEFTIGE VERKAUFS- UND VERTRIEBSSTRATEGIE]
Adrian vonDoernberg *In its* Lufthansa Yearbook 1992 Oct. 1992 p 156-165 In GERMAN (For primary document see N94-28230 07-03)
Copyright Avail: CASI HC A02/MF A03

The commercial strategy of Lufthansa for reacting to air traffic changes is described. A stricter organization structure was developed for marketing and selling. An offensive marketing communication program was developed for defining the Lufthansa product on the market and for dismantling selling barriers by customers and dispatch clerks. The partnership concept was used to enhance cooperation with middle class travel agencies; regional offices created customer advisory boards in order to maintain narrow contacts with users. The passenger service was improved with a new customer system: bonus program, accelerated check-in, self service facilities and better lounges are now proposed. Lufthansa decided these modifications in order to assess its leadership on quality, considering the increasing concurrence of the strongly growing private travel market. ESA

The air transportation market towards countries from East Europe is investigated. Germany is geographically the biggest turntable in Europe for West to East air traffic. Lufthansa is a leader on this market with 220 flights per week to 14 East European towns and offers its technology and knowhow to former communist countries in order for infrastructure problems, such as communication, maintenance and safety deficiencies, to be solved. The concurrence is strong in East European transportation, since air companies can offer low price products and are buying modern, western aircraft; Lufthansa decided to open offices in all capitals in order to protect its leadership. The role of Boeing 727 in Lufthansa operations is explained. Lufthansa ordered the first Boeing 727 in 1961, which had a cruise velocity of 900 kph and could land on short runways. During thirty years, 61 Europa Jets from several generations flew for Lufthansa and showed high safety and reliability performances; nine quick change versions were bought so that the transformation in 25 minutes from a passenger aircraft to a cargo aircraft was possible. From the beginning, Boeing 727 was regarded by the passengers as the most comfortable civil aircraft. In 1992 Autumn the last Boeing 727 are replaced by A-320 aircraft, whose specific consumption and loading on environment are lower. It is noticed that Lufthansa Boeing 727 carried 60 million passengers 500 million km. ESA

A SYMBOL OF RELIABILITY: Ju 52 [SYMBOL DER ZUVERLAESSIGKEIT: DIE JU 52] **c05**
Ralf Nolting *In its* Lufthansa Yearbook 1992 Oct. 1992 p 186-191 In GERMAN (For primary document see N94-28230 07-03)
Copyright Avail: CASI HC A02/MF A03

The story of Junker 52 (Ju 52) aircraft is presented. Lufthansa possessed 78 machines of this type in 1940 and in 1985 wished to find at least one JU 52 as a symbol of aviation tradition, German knowhow as pioneer aircraft. A Ju 52 was found in Florida and sent to Germany. The old aircraft was restored during sixteen months and its structure and turbines were totally overhauled; the cabin was equipped with new seats and the cockpit with modern navigation instruments. The renewed aircraft flew for eight months over the U.S. and ended its trip by a formation flight with a Boeing 737 aircraft above Seattle. The turbine engines were modified for noise reduction. ESA

AIRBORNE DATA LINK OPERATIONAL EVALUATION TEST PLAN
Albert J. Rehmann and R. H. Mogford (Computer Technology Associates, Inc., Pleasantville, NJ.) Aug. 1993 47 p
(AD-A274096; DOT/FAA/CT-TN93/30) Avail: CASI HC A03/MF A01

This plan describes an end-to-end study of operational concepts and procedures associated with the introduction of electronic data communications between flight crews and air traffic controllers. Full performance controllers from terminal facilities will interact with type-related line pilots in four cockpit simulators networked into the Federal Aviation Administration Technical Center's Air Traffic Control Laboratory. Measures of human performance will gain insight into flight crew alerting, display, placement, and the utility of voice annunciation of data link messages. Direct measures of workload, communications efficiency, data link attention time (measured by head position), and aircraft state will be gathered and translated into recommendations for the cockpit display configuration. DEAD RECKONING NAVIGATION
Hannu Hakala Sep. 1992 88 p Sponsored by Technology Development Center, Finland
(ISSN 1235-0605)
(VTT-TIED-1402; ISBN-951-38-4216-9; ETN-94-95249) Copyright Avail: CASI HC A05/MF A01

Navigation systems for automotive navigation are considered. Basic in-car navigation is based on dead reckoning, which is enhanced with methods like map matching, proximity beacons, or satellite navigation systems. The method of dead reckoning in vehicle navigation applications is described. The terminology used in this area is explained. The basic theory of dead reckoning is given. The principles of common types of odometers and differential odometer are described. Examples of odometer realizations and distance measurement devices are presented. The other component of dead reckoning calculations, heading, can be measured with magnetic compasses, gyroscopes, optical gyros, and other means. These methods are explained and component realizations are shown. Inertial navigation systems are described. Dead reckoning and inertial navigation methods are compared. ESA

ANALYSIS AND SIMULATION OF A GPS RECEIVER DESIGN USING COMBINED DELAY-LOCK AND MODIFIED TANLOCK LOOPS M.S. Thesis
George D. Harris Dec. 1993 93 p
(AD-A274037; AFIT/GE/ENG/93D-13) Avail: CASI HC A05/MF A01

The purpose of this thesis was to investigate the performance of two types of tracking loops used in global positioning system (GPS) receivers. The first loop, the delay-lock loop (DLL), is responsible for maintaining synchronization with the received PN sequence. The second loop, the modified tanlock loop (MTLL), is responsible for maintaining synchronization with the carrier signal. The performance of the two loops is investigated first separately then their performance is evaluated when operated together. This thesis is an investigation on the ability of these two loops to overcome corruption of the input signal due to noise. Expanding the dynamic operating range of these loops can significantly improve GPS receiver operation. Results indicate the performance of the loops was better than theoretical predictions by maintaining lock across a wide range of loop gains and SNR's. However, when the loops were combined, the loops did not perform as predicted by theory. All simulations display phenomena which was not present in the theoretical predictions. DTIC

AIR TRAFFIC CONTROLLER WORKING MEMORY: CONSIDERATIONS IN AIR TRAFFIC CONTROL TACTICAL OPERATIONS Technical Report, Oct. 1992 - Sep. 1993
Earl S. Stein and Daniel Garland Sep. 1993 71 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273722; DOT/FAA/CT-TN-93/37) Avail: CASI HC A04

The Air Traffic Control (ATC) environment is characterized by a continuous sequence of ever-changing, transient information, such as a series of aircraft being handled by an air traffic controller which must be encoded and retained, primarily, for tactical use (3 to 5 minutes) and secondarily, for strategic planning. This information is complicated by the limitations and constraints of human memory, in particular, working memory. Working memory can potentially degrade performance. The primary objective of this report is to raise an awareness of the memory requirements of ATC tactical operations by presenting information on working memory processes that are relevant to ATC tasks, and the vulnerability of these processes to disruption. This report focuses on developing an understanding of the role working memory plays in air traffic controller performance by emphasizing the constraints, and the factors that may overcome or minimize memory loss of critical ATC information. Two hundred twenty-nine references are cited in this report. DTIC

DIFFERENTIAL GLOBAL POSITIONING SYSTEM FOR THE SURFACE-TOWED ORDNANCE LOCATING SYSTEM: TESTING, RESULTS, AND USER'S GUIDE
T. L. Stewart and C. W. Hubbard Oct. 1993 64 p
(Contract DE-AC06-76RL-01830)
(DE94-002980; PNL-8921) Avail: CASI HC A04/MF A01

Researchers at the Pacific Northwest Laboratory integrated and tested a Global Positioning System (GPS) for use with the Naval Explosive Ordnance Disposal Technology Center's (NEODTC) Surface-Towed Ordnance Locating System (STOLS). The GPS automatically and continuously provides latitude, longitude, and elevation information at the mobile GPS unit. The results of testing the GPS are shown in this report. The results reveal accuracies in the submeter range in real time and within a few centimeters using post-processing software. A description of hardware and software components is also included, along with system drawings and parts lists. DOE

MIMO RECURSIVE LEAST SQUARES CONTROL ALGORITHM FOR THE AN/FPN-44A LORAN-C TRANSMITTER M.S. Thesis
John D. Wood Sep. 1993 107 p
(AD-A274820) Avail: CASI HC A06/MF A02

A multiple-input, multiple-output (MIMO) recursive least squares (RLS) algorithm is developed to shape and control the Loran-C RF pulse of the AN/FPN-44A tube type transmitter. The control algorithm is incorporated into a transmitter simulation program, where it seeks to produce an optimal transmitter drive waveform (TDW). An optimal TDW produces a near ideal RF pulse. The control algorithm uses a MIMO reference model of the transmitter; parameters of the model are obtained using recursive least squares multichannel time series techniques. The MIMO reference model has the ability to adapt to the non-LTI characteristics of the simulated transmitter. The MIMO RLS control algorithm is implemented in both an ideal and a realistic noisy environment. In the ideal environment, when representing the RF pulse with parameters of its half-cycle peak amplitudes and zero-crossings, the MIMO RLS controller is able to shape the RF pulse and control its zero-crossings. Quantization and system noise in the non-ideal environment results in performance deterioration of the control algorithm. The performance of the MIMO RLS algorithm is compared against another method of control, the steepest descent algorithm. DTIC

ROTORCRAFT LOW ALTITUDE IFR BENEFIT/COST ANALYSIS: CONCLUSIONS AND RECOMMENDATIONS Final Report
Robert K. Anoll, Robert B. Newman, and Edwin D. McConkey Oct. 1993 153 p
(Contract DTFA01-87-C-00014)
(AD-A274241; SCT-92RR-8; DOT/FAA/RD-93/22) Avail: CASI HC A08/MF A02

The Rotorcraft Master Plan advocates the establishment of additional communications, navigation, and surveillance (CNS) facilities, as well as the analysis and development of systems to satisfy the increasing demand for widespread instrument flight rules (IFR) rotorcraft operations within the National Airspace System (NAS). The objective of this study is to determine if there is an economic basis for improvement of these low altitude IFR services within the NAS in order to better support rotorcraft IFR operations. The findings of this study will aid FAA decision making in that regard. In view of prior implementation decisions on LORAN-C and GPS, the emphasis in this effort is on communications, surveillance, procedural changes, and avionics. This report is the last of a series of three reports that address rotorcraft low altitude benefit/cost analysis. This final report reviews the operational requirements and constraints for specific rotorcraft missions identified in the previous reports in this series. It also reviews all of the alternatives identified for improving rotorcraft operations. The alternatives considered include additional communications and surveillance equipment, both existing equipment and future systems identified in the Aviation Systems Capital Investment Plan (CIP), and the air traffic control (ATC) procedural changes. A benefit/cost (B/C) analysis is conducted for each communication, surveillance, and procedural improvement identified. DTIC

DEVELOPMENT OF A PERFORMANCE EVALUATION TOOL (MMSOFE) FOR DETECTION OF FAILURES WITH MULTIPLE MODEL ADAPTIVE ESTIMATION (MMAE) M.S. Thesis
Robert L. Nielsen Dec. 1993 180 p
(AD-A274218; AFIT/GE/Eng/93S-37) Avail: CASI HC A09/MF A02

Multiple model Kalman Filter (KF) techniques are used extensively for Multiple Model Adaptive Estimation (MMAE), Multiple Model Adaptive Control (MMAC), and Distributed Kalman Filter (DKF) applications to determine Bayesian-blended optimal estimates of states, uncertain parameters, and optimal control signals. Multiple model methods are used for sensor management, Failure Detection and Isolation (FDI), and other Guidance and Control (G and C) applications. A simulation tool called the Multiple Model Simulation for Optimal Filter Evaluation (MMSOFE) has been in this research. MMSOFE is based on the well-benchmarked single Kalman filter tool called Multimode Simulation for Optimal Filter Evaluation (MSOFE). MMSOFE is a highly portable and versatile multiple and single Kalman filter evaluation tool. It is capable of performing simulations with one filter or up to 98 elemental filters in a multiple model adaptive filter structure. It can be adapted easily for other multiple model applications. MMSOFE was applied to failure detection and isolation of measurement jamming and spoofing-type failures, similar to jamming and spoofing of a Global Positioning System (GPS). A satellite orbit estimation test case was used. DTIC

A system for automatic real-time verification of the fault monitoring of an executive monitor of a microwave landing system (MLS) is disclosed. When an internally generated out-of-tolerance or erroneous signal is detected by the monitor, the system generates an alarm and declares it valid. The system also includes a station control board connected on line with the executive monitor which provides a signal to the monitor representative of erroneous or out-of-tolerance data in order to initiate an alarm in the executive monitor. The actual data obtained by the executive monitor is stored until proper fault monitoring verification occurs. A filter counting means is employed to record a history of the out-of-tolerance data received by the executive monitor so that the filter counting means can be preconditioned during the verification process to receive one additional out-of-tolerance sample to thereby generate an alarm within the executive monitor. A switch is used to permit an internally generated out-of-tolerance sample to be analyzed instead of the sampled information generated by the antenna system. Author (CISTI)

PACKET RADIO DATA LINK APPLICATIONS IN THE NASA LANGLEY RESEARCH CENTER TRANSPORT SYSTEMS RESEARCH VEHICLE
Wesley C. Easley, Donald Carter, and David G. McLuer (Lockheed Engineering and Sciences Co., Hampton, VA.) Jan. 1994 30 p
(RTOP 505-64-13-11)
(NASA-TM-109071; NAS 1.15:109071) Avail: CASI HC A03/MF A01

An amateur packet radio system operating in the very high frequency (VHF) range has been implemented in the Transport Systems Research Vehicle at the NASA Langley Research Center to provide an economical, bidirectional, real-time, ground-to-air data link. The packet system has been used to support flight research involving air traffic control (ATC), differential global positioning systems (DGPS), and windshear terminal doppler weather radar (TDWR). A data maximum rate of 2400 baud was used. Operational reliability of the packet system has been very good. Also, its versatility permits numerous specific configurations. These features, plus its low cost, have rendered it very satisfactory for support of data link flight experiments that do not require high data transfer rates. Author (revised)

DIFFERENTIAL GPS METHODS AND PERFORMANCE FOR MARINE APPLICATIONS Final Report
Gerard Lachapelle Jan. 1993 58 p
(Contract DREP-W7708-2-0529/01-XSA)

(DREP-93-09; DSIS-94-00049; CTN-94-61119) Avail: CASI HC A04/MF A01

A survey is provided of current and emerging technology in differential dynamic global positioning systems (GPS), particularly in the marine environment. Measures of accuracy for GPS positions are defined. Error sources in GPS include receiver noise, multipath reflection, combined receiver noise and multipath, orbital errors, loss of phase lock, cycle slip detection and recovery, ionospheric group delay and carrier phase advance, ionospheric scintillation, tropospheric refractivity, and selective availability. The concepts of differential GPS are outlined along with a description of algorithms and procedures. Differential GPS reduces or eliminates orbital, ionospheric, tropospheric, selective availability, and clock errors and provides better quality control, but amplifies the remaining errors. Measured performance of differential GPS systems are summarized, with emphasis on new technology and algorithms. These algorithms and technologies include single and double difference methods, carrier phase smoothing, and carrier phase ambiguity resolution. Results are presented for a case study examining the performance of P code receivers and high performance C/A code receivers in a survey launch environment. Future issues and trends in differential GPS are addressed in the areas of equipment, methodologies, and infrastructure. Author (CISTI)

REFINEMENT FOR FAULT-TOLERANCE: AN AIRCRAFT HAND-OFF PROTOCOL
Keith Marzullo, Fred B. Schneider, and Jon Dehn Apr. 1994 20 p
(Contracts NAG2-593; N00140-87-C-8904; N00014-91-J-1219; NSF CCR-87-01103; NSF CCR-90-14363)
(NASA-CR-195697; NAS 1.26:195697; TR-94-1417) Avail: CASI HC A03/MF A01

Part of the Advanced Automation System (AAS) for air-traffic control is a protocol to permit flight hand-off from one air-traffic controller to another. The protocol must be fault-tolerant and, therefore, is subtle -- an ideal candidate for the application of formal methods. This paper describes a formal method for deriving fault-tolerant protocols that is based on refinement and proof outlines. The AAS hand-off protocol was actually derived using this method; that derivation is given. Author

FLIGHT TESTING OF GPS AND GPS-AIDED SYSTEMS
O. B. M. Pietersen, M. A. G. Peters, and N. vanDriel 16 Mar. 1992 17 p Presented at the 80th AGARD Flight Mechanics Panel on Flight Testing Symposium, Chania, Crete, 11-14 May 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NLR-TP-92151-U; ETN-94-95444) Avail: CASI HC A03

Flight test programs carried out are described: trials to investigate the suitability of differential global positioning system (GPS) for precision approaches; trials to determine the advantages of aiding a GPS receiver by inertial navigation system (INS) and of the use of null steering antennas; and trials to evaluate an in house developed navigation filter in which three navigation sensors, GPS, INS, and terrain referenced navigation (TRN), were integrated. An integrated navigation system is concluded to offer a greater robustness and a higher accuracy of the navigation solution, taking into account the weaknesses the individual sensors have. Differential GPS can eliminate a number of systematic errors, improving the attainable accuracy. ESA

AIRCRAFT MANEUVERS FOR THE EVALUATION OF FLYING QUALITIES AND AGILITY. VOLUME 1: MANEUVER DEVELOPMENT PROCESS AND INITIAL MANEUVER SET Final Report, 1 Sep. 1990 - 1 Jun. 1993
David J. Wilson, David R. Riley, and Kevin D. Citurs Aug. 1993 165 p
(Contract F33615-90-C-3600)
(AD-A273913; WL-TR-93-3081) Avail: CASI HC A08/MF A02

A set of aircraft maneuvers has been developed to augment evaluation maneuvers used currently by the flying qualities and flight test communities. These maneuvers extend evaluation to full aircraft dynamics throughout the aircraft flight envelope. As a result, a tie has been established between operational use and design parameters without losing control of the aircraft evaluation process. Twenty maneuvers are described as an initial set to examine primarily high angle of attack conditions. Perhaps as important as the maneuvers themselves is the method used to select them. These maneuvers will allow direct measurement of flying qualities throughout the flight envelope instead of merely comparing parameters to specification values. DTIC

WEAPON SYSTEM INTEGRATION FOR THE AFIT VIRTUAL COCKPIT M.S. Thesis
William E. Gerhard, Jr. 1993 67 p
(AD-A274058; AFIT/GCS/Eng/93D-10) Avail: CASI HC A04/MF A01

The Air Force Institute of Technology is continuing research in the Virtual Cockpit. The Virtual Cockpit makes use of high performance graphics workstations, Virtual Environment technology, and Distributed Interactive Simulation network protocols to create a flight simulator based on the capabilities of the McDonnell Douglas F-15E Strike Eagle. The work presented in this thesis focuses on the design and implementation issues for integrating a weapons delivery capability. Weapons simulated include the following: RADAR and IR guided air-to-air missiles, gravity and precision guided bombs, and a 20mm cannon. Virtual Environment displays used include the following: color NTSC and monochrome high resolution helmet mounted displays employing a Polhemus Fastrack sensor, and a display using five separate BARCO projectors simultaneously. The Target graphics system was a four processor, SGI Onyx workstation with a Reality Engine graphics pipeline. Graphics rendering was accomplished with an AFIT developed object oriented simulation software package based on the SGI Performer 1.2 application development environment. DTIC

EVALUATION OF MODERATE ANGLE OF ATTACK ROLL OF A DUAL ENGINE, THRUST VECTORING AIRCRAFT USING QUANTITATIVE FEEDBACK THEORY M.S. Thesis
Kevin E. Boyum Dec. 1993 207 p
(AD-A274118; AFIT/GE/ENG/93D-01) Avail: CASI HC A10/MF A03

This thesis develops an innovative approach to the design of a flight control system for performing the large-amplitude velocity vector roll maneuver at high angles of attack (AOA's). A six degree of freedom aircraft model is developed from the fundamental nine-state equations of motion using a modified linearization technique. The MIMO (multiple-input multiple-output) Quantitative Feedback Theory (QFT) robust control design technique is then used to jointly address the system nonlinearities present in this maneuver and the changes in the system parameters due to changes in flight condition, treating them as structured uncertainty in the design of a three-axis rate-commanded control system. The development of a weighting matrix, based on the fundamentals of the aileron-rudder interconnect, aids in this design process. Nonlinear six degree-of-freedom closed-loop control system simulations demonstrate the accuracy of the developed models, the validity of the QFT designed compensator and prefilter, and the successful initiation and arrest of the velocity vector roll maneuver. EGADS: A MICROCOMPUTER PROGRAM FOR ESTIMATING THE AERODYNAMIC PERFORMANCE OF GENERAL AVIATION AIRCRAFT
John E. Melton Jan. 1994 57 p
(RTOP 505-59-53)
(NASA-TM-104013; A-93066; NAS 1.15:104013) Avail: CASI HC A04/MF A01

EGADS is a comprehensive preliminary design tool for estimating the performance of light, single-engine general aviation aircraft. The software runs on the Apple Macintosh series of personal computers and assists amateur designers and aeronautical engineering students in performing the many repetitive calculations required in the aircraft design process. The program makes full use of the mouse and standard Macintosh interface techniques to simplify the input of various design parameters. Extensive graphics, plotting, and text output capabilities are also included. Author (revised)

DESIGN OPTIMIZATION OF HIGH-SPEED PROPROTOR AIRCRAFT
David R. Schleicher, James D. Phillips, and Kevin B. Carbajal Apr. 1993 40 p
(RTOP 505-69-36)
(NASA-TM-103988; A-93010; NAS 1.15:103988) Avail: CASI HC A03/MF A01

NASA's high-speed rotorcraft (HSRC) studies have the objective of investigating technology for vehicles that have both low downwash velocities and forward flight speed capability of up to 450 knots. This paper investigates a tilt rotor, a tilt wing, and a folding tilt rotor designed for a civil transport mission. Baseline aircraft models using current technology are developed for each configuration using a vertical/short takeoff and landing (V/STOL) aircraft design synthesis computer program to generate converged vehicle designs. Sensitivity studies and numerical optimization are used to illustrate each configuration's key design tradeoffs and constraints. Minimization of the gross takeoff weight is used as the optimization objective function. Several advanced technologies are chosen, and their relative impact on future configurational development is discussed. Finally, the impact of maximum cruise speed on vehicle figures of merit (gross weight, productivity, and direct operating cost) is analyzed. The three most important conclusions from the study are payload ratios for these aircraft will be commensurate with current fixed-wing commuter aircraft; future tilt rotors and tilt wings will be significantly lighter, more productive, and cheaper than competing folding tilt rotors; and the most promising technologies are an advanced-technology proprotor for both tilt rotor and tilt wing and advanced structural materials for the folding tilt rotor. AN ANALYSIS OF MULTIPLE SENSOR SYSTEM PAYLOADS FOR UNMANNED AERIAL VEHICLES M.S. Thesis
John F. Keane Sep. 1993 101 p
(AD-A274905) Avail: CASI HC A06/MF A02

Unmanned aerial vehicles (UAV's) presently under consideration by the Program Executive Officer for Cruise Missile Projects and Unmanned Aerial Vehicles (PEOCNPUAV) will be equipped solely with electrooptical (EO) sensors. This thesis provides a comparative analysis of the mission effectiveness between UAV's equipped with EO sensors and those equipped with a multiple sensor system payload. A historical review of UAV development and employment is provided so that the reader may gain some insight into past UAV shortcomings in the hopes that they might be prevented in future systems. A typical reconnaissance, surveillance, and target acquisition (RSTA) mission scenario is defined and a comparison made between UAV's equipped with EO sensors and those equipped with multiple sensor system payloads. The measure of effectiveness used for this comparison is the time required by the UAV to search 100 percent of an assigned area. The physical and operating characteristics of available sensor systems are discussed in detail. An optimization model is developed for selecting multiple sensor payloads from those sensor systems described. The model considers the sensor's physical characteristics, unit cost, identification capability, and false alarm rate when determining the optimum payload. The optimum sensor system payloads are selected and the best alternatives to EO sensors for performing RSTA missions in a hostile environment are recommended under a range of budgets. DTIC

ANALYSIS AND OPTIMIZATION OF PRELIMINARY AIRCRAFT CONFIGURATIONS IN RELATIONSHIP TO EMERGING AGILITY METRICS Final Report, 15 Sep. 1991 - 14 Sep. 1993

Doral R. Sandlin and Brent Alan Bauer Dec. 1993 133 p
(Grant NAG2-743)
(NASA-CR-195228; NAS 1.26:195228) Avail: CASI HC A07/MF A02

This paper discusses the development of a FORTRAN computer code to perform agility analysis on aircraft configurations. This code is to be part of the NASA-Ames ACSYNT (AirCraft SYNThesis) design code. This paper begins with a discussion of contemporary agility research in the aircraft industry and a survey of a few agility metrics. The methodology, techniques and models developed for the code are then presented. Finally, example trade studies using the agility module along with ACSYNT are illustrated. These trade studies were conducted using a Northrop F-20 Tigershark aircraft model. The studies show that the agility module is effective in analyzing the influence of common parameters such as thrust-to-weight ratio and wing loading on agility criteria. The module can compare the agility potential between different configurations. In addition one study illustrates the module's ability to optimize a configuration's agility performance. Author

EFFECTS OF PLASTIC MEDIA BLASTING ON AIRCRAFT SKIN Final Report

Charles C. Chen, Mark Muller, and John W. Reinhardt Nov. 1993 113 p
(Contract DTFA03-89-C-00043)
(AD-A274817; DOT/FAA/CT-91/27) Avail: CASI HC A06/MF A02

The use of methylene chloride chemical solvents in aviation paint removal is becoming increasingly unacceptable in view of restrictive Environmental Protection Agency (EPA) regulations. A readily available alternative, plastic media blasting (PMB), must be examined for its effects on the thin aluminum used as skin material in civilian aircraft. This study examines the effects of plastic media blasting or the crack propagation rates of 2024-T3 aluminum in alclad of 0.032, 0.040, 0.050 inch thickness, and in anodized of 0.032, 0.040, and 0.050 inch thickness. A technical search was performed for the following topics: (1) fatigue crack growth (FCG) rate comparison between PMB and chemical stripping, (2) effects of heavy particulate contamination on the fatigue life of aircraft skin, (3) acceptable level of contamination in the plastic media, (4) effects of multiple strippings on FCG, (5) maximum number of strippings allowed, and (6) specifications of controlled parameters to safely operate a PMB system. Fatigue crack propagation tests, Almen strip tests, Scanning Electron Microscope (SEM) photography, and surface toughness measurements were conducted. The results of the technical search and the tests performed are presented, as well as supplementary Almen strip arc height data. This study also presents an overview of nine alternative aviation paint stripping methods in terms of paint stripping effectiveness, substrate damage, environmental impact, health impact, and cost. COMPUTER CODE FOR INTERACTIVE ROTORCRAFT PRELIMINARY DESIGN USING A HARMONIC BALANCE METHOD FOR ROTOR TRIM M.S. Thesis

Robert K. Nicholson, Jr. 23 Sep. 1993 91 p
(AD-A274924) Avail: CASI HC A05/MF A01

The Joint Army/Navy Rotorcraft Analysis and Design (JANRAD) computer program was developed to aid in the analysis of helicopter rotor performance, stability and control, and rotor dynamics. JANRAD is an interactive, user friendly program, capable of accurately and quickly solving helicopter design problems at the preliminary design level. The program was written as a collection of MATLAB script and function files (M-files) using the 386-MATLAB version 3.5 programming language. The M-file janrad.in invokes the user interface routines and calls various analysis modules (M-files) which contain the appropriate analysis and output routines. Each of these modules use a common routine, trim.m, which employs blade element theory and a harmonic balance method for rotor trim. The program is limited to conditions of steady flight with no winds and is accurate at a hover and for forward airspeeds greater than or equal to 50 knots. DTIC

EXPERIMENTAL INVESTIGATION OF ADVANCED HUB AND PYLON FAIRING CONFIGURATIONS TO REDUCE HELICOPTER DRAG

D. M. Martin (Sterling Software, Inc., Palo Alto, CA.), R. W. Mort (Bell Helicopter Co., Fort Worth, TX.), L. A. Young, and P. K. Squires (Bell Helicopter Co., Fort Worth, TX.) Sep. 1993 93 p
(RTOP 505-59-36)
(NASA-TM-4540; A-93079; NAS 1.15:4540) Avail: CASI HC A05/MF A01

New hub and pylon fairing designs were tested on a one-fifth scale Bell Helicopter Textron Model 222 helicopter with a bearingless main rotor hub. The blades were not installed for this test. The fairings were designed by NASA and Bell Helicopter Textron under a joint program and tested in the Ames Research Center 7-by 10-Foot Wind Tunnel. All six aircraft forces and moments were measured using the tunnel scales system. Previous research has identified the integrated hub and pylon fairing approach as the most efficient in reducing helicopter drag. Three hub fairings and three pylon fairings were tested (in various combinations) resulting in a total of 16 different configurations, including the baseline helicopter model without fairings. The geometry of the new fairings is described in detail. Test results are presented in the form of plots of the six model forces and moments. The data show that model drag can be reduced by as much as 20 percent by combining a small hub fairing (that has a circular arc upper surface and a flat lower surface) integrated with a nontapered pylon fairing. To minimize drag, the gap between the lower surface of the hub and upper surface of the pylon fairing must be kept to a minimum. Results show that the aerodynamic effects of the fairings on static longitudinal and directional stability can also be important. Author (revised)

A TECHNIQUE FOR INTEGRATING ENGINE CYCLE AND AIRCRAFT CONFIGURATION OPTIMIZATION Final Report

Karl A. Geiselhart Feb. 1994 77 p
(Contract NAS1-19000; RTOP 505-69-50-01)
(NASA-CR-191602; NAS 1.26:191602) Avail: CASI HC A05/MF A01

A method for conceptual aircraft design that incorporates the optimization of major engine design variables for a variety of cycle types was developed. The methodology should improve the lengthy screening process currently involved in selecting an appropriate engine cycle for a given application or mission. The new capability will allow environmental concerns such as airport noise and emissions to be addressed early in the design process. The ability to rapidly perform optimization and parametric variations using both engine cycle and aircraft design variables, and to see the impact on the aircraft, should provide insight and guidance for more detailed studies. A brief description of the aircraft performance and mission analysis program and the engine cycle analysis program that were used is given. A new method of predicting propulsion system weight and dimensions using thermodynamic cycle data, preliminary design, and semi-empirical techniques is introduced. Propulsion system performance and weights data generated by the program are compared with industry data and data generated using well established codes. The ability of the optimization techniques to locate an optimum is demonstrated and some of the problems that had to be solved to accomplish this are illustrated. Results from the application of the program to the analysis of three supersonic transport concepts installed with mixed flow turbofans are presented. The results from the application to a Mach 2.4, 5000 n.mi. transport indicate that the optimum bypass ratio is near 0.45 with less than 1 percent variation in minimum gross weight for bypass ratios ranging from 0.3 to 0.6. In the final application of the program, a low sonic boom fix a takeoff gross weight concept that would fly at Mach 2.0 overwater and at Mach 1.6 overland is compared with a baseline concept of the same takeoff gross weight that would fly Mach 2.4 overwater and subsonically overland. The results indicate that for the design mission, the low boom concept has a 5 percent total range penalty relative to the baseline. Additional cycles were optimized for various design overland distances and the effect of flying off-design overland distances is illustrated. Author (revised)

TESTS OF HIGHLY LOADED SKIDS ON A CONCRETE RUNWAY
Sandy M. Stubbs and Robert H. Daugherty Mar. 1994 19 p
(RTOP 505-63-10-02)
(NASA-TP-3435; L-17324; NAS 1.60:3435) Avail: CASI HC A03/MF A01

Skids have been used at various times for aircraft landing gear ever since the Wright Flyer appeared in the early 1900's. Typically, skids have been employed as aircraft landing gear either at low speeds or at low bearing pressures. Tests were conducted to examine the friction and wear characteristics of various metals sliding on a rough, grooved concrete runway. The metals represented potential materials for an overload protection skid for the Space Shuttle orbiter. Data from tests of six skid specimens conducted at higher speeds and bearing pressures than those of previous tests in the open literature are presented. Skids constructed of tungsten with embedded carbide chips exhibited the lowest wear, whereas a skid constructed of Inconel 718 exhibited high wear rates. Friction coefficients for all the skid specimens were moderate and would provide adequate stopping performance on a long runway. Because of its low wear rate, a skid constructed of tungsten with embedded carbide chips is considered to be a likely candidate for an aircraft skid or overload protection skid. Author (revised)

DEVELOPMENT AND EVALUATION OF A NEAR INFRARED REFLECTING AND LOW VISIBILITY PAINT SCHEME FOR RAAF P-3C ORION AIRCRAFT
L. V. Wake Oct. 1993 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A274881; MRL-TR-93-35; DODA-AR-008-565) Avail: CASI HC A03

In this report, the development and trialling of a tactical, low visibility paint scheme (LVPS) for RAAF P-3C Orion aircraft is discussed. The LVPS was formulated in grey colors using solar heat reflecting pigments to reduce overheating problems which had resulted in the abandonment of an earlier camouflage trial. The paint scheme, which is one of several schemes under consideration by RAAF, employs strict countershading principles with pale grey underneath the aircraft, light grey on the fuselage sides and vertical flight control surfaces and mid-grey on top of the fuselage and upper flight control surfaces. Evaluation of the paint scheme was carried out at RAAF Edinburgh under summertime conditions and showed that the increase in heat load by use of the solar heat reflecting paint scheme (SHR)-LVPS on the Environmental Control System (ECS) of the aircraft was 0.53 kW compared with the existing paint scheme. This compares favorably with the reported heat load increase of 1.7 kW for counter-shaded aircraft using conventionally formulated grey paints. It is concluded that the use of the SHR-LVPS would have essentially no effect on P-3C operational temperatures except under severe environmental conditions where an increase in temperatures of 0.3 C in the cabin and 1.3 C at the flight stations could be expected. EXPERIMENTAL STUDY OF THE ANGLED CRACK IN GLARE 3
K. J. J. M. Zaal 1994 66 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-126554; M-667) Avail: Issuing Activity (National Technical Information Service (NTIS))

The aim of the present investigation is to perform both an experimental and a theoretical study of the behavior of cracks in GLARE loaded under a combined mode I and mode II loading, using the angled crack problem. Cracks originating from impact damage in aircraft fuselages can experience a mixed mode I and II load at the start of their life. For GLARE, the more fibrous nature of GLARE compared to aluminum may change the propagation. The experiments were performed on specimens made of GLARE-3, with the main material directions aligned with the specimen axis. As reference materials, both aluminum 2024-T3 and 7075-T6 are used. For angled cracks, the propagation direction has been predicted by Erdogan and Sih, Williams and Ewing and Theocaris et al. NTIS

DEVELOPMENT OF FIBRE-METAL LAMINATES, ARALL AND GLARE, NEW FATIGUE RESISTANT MATERIALS
J. Schijve Jan. 1993 25 p Presented at the 1993 FATIGUE, Montreal, Ontario, 3-7 May 1993 See also N90-26368 and PB92-133412
(PB94-126471; LR-715) Avail: CASI HC A03/MF A01

Research on adhesive-bonded sheet metal laminates (such as ARALL and GLARE) is described as a predecessor of a new class of materials, the fiber-metal laminates. It is explained why fiber-metal laminates have such a high fatigue resistance, especially against fatigue crack growth. Additional advantages of the barrier function of the fiber layers are indicated. Applications are discussed. Comments are made on developing a material for practical applications. NTIS

METHODS FOR EXPERIMENTALLY DETERMINING COMMERCIAL JET AIRCRAFT LANDING PARAMETERS FROM VIDEO IMAGE DATA Final Report
Richard P. Micklos and Thomas DeFiore Aug. 1993 60 p
(Contract DTFA03-92-Z-0029)
(AD-A274207; DOT/FAA/CT-93/7) Avail: CASI HC A04/MF A01

As part of its Aging Aircraft Research Program, the Federal Aviation Administration is establishing a passive system of measuring aircraft landing contact parameters at commercial airports. This research involves the broader application of recent US NAVY technology used to measure landing contact conditions of Navy carrier aircraft and develop/assess Navy landing loads design criteria. This technique is based on digitizing and analyzing high resolution video images recorded by cameras strategically stationed along the runway apron, and it does not require the installation of any instrumentation on the aircraft or changes to normal aircraft operating procedures. This report describes the application of the Navy's latest procedures for precisely determining the kinematics of typical commercial aircraft landings and provides the results of a demonstration survey conducted at the Federal Aviation Administration (FAA) Technical Center in June 1992. In addition, the proposed runway camera configuration for a production landing survey at a high volume airport is presented. DTIC

COMPOSITE LEADING EDGE/SPAR MEMBER FOR AN AIRCRAFT CONTROL SURFACE Patent
Rudolf Braun, inventor (to Boeing) and Richard Jensen, inventor (to Boeing) 4 Jan. 1994 24 p
(CA-Patent-1-325-765; Int-Patent-Class-B32B-031/24; CTN-94-61094)
Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A one-piece composite leading edge/spar member for an aircraft control

surface is provided which is of a lighter and stronger construction offering dimensional stability. An efficient method for manufacturing the member is also disclosed. The member of the invention includes a forward leading edge portion and an aft spar portion, which are connected together as a continuous one-piece tubular member of composite material. The forward leading edge portion may be rounded, and the aft spar portion may include an aft web portion and first and second rebate portions. The rebate portions connect the web portion to the rounded forward leading edge portion, and provide surfaces for the attachment of skin surface members. In a preferred mode of fabricating the member, a composite material is applied or wrapped around a mandrel, with the material perimetrically surrounding and covering the rounded leading edge and the spar forming portions of the mandrel. A forming pressure may then be applied to the composite material to shape and mold the material into the same shape as the rounded leading edge and spar forming portions. This method permits the composite material to be filament wound around the mandrel instead of being wrapped on a layer by layer basis. Filament winding would be particularly well suited for mass production of leading edge/spar members of the invention.

PROCEEDINGS OF THE NON-LINEAR AERO PREDICTION REQUIREMENTS WORKSHOP
Michael J. Logan, ed. Mar. 1994 163 p Workshop held in Hampton, VA, 8-9 Dec. 1993 Sponsored by NASA, Washington
(RTOP 505-68-70-09)
(NASA-CP-10138; NAS 1.55:10138) Avail: CASI HC A08/MF A02

The purpose of the Non-Linear Aero Prediction Requirements Workshop, held at NASA Langley Research Center on 8-9 Dec. 1993, was to identify and articulate requirements for non-linear aero prediction capabilities during conceptual/preliminary design. The attendees included engineers from industry, government, and academia in a variety of aerospace disciplines, such as advanced design, aerodynamic performance analysis, aero methods development, flight controls, and experimental and theoretical aerodynamics. Presentations by industry and government organizations were followed by panel discussions. This report contains copies of the presentations and the results of the panel discussions. Author (revised)

THE DEVELOPMENT OF AN IN-MOTION RADIOGRAPHY SYSTEM FOR LARGE AREA AIRCRAFT SCANNING
Richard D. Finlayson, John K. Cornes, Dan S. Liesch, and William R. Sturrock Jul. 1993 22 p
(DREP-TM-93-53; DSIS-94-00099; CTN-94-61118) Avail: CASI HC A03/MF A01

An in-motion radiography system (IMRS) includes a portable x-ray unit, adapted for the requirements of in-motion radiography, and an x-y scanning arrangement to allow large area scanning. Two separate IMRS experiments were performed, each with a different slit length set on a focusing collimator. A long slit length allowed a fast scan that exposed the film in one pass of the x-ray tube, creating a low resolution radiograph. A shorter slit length was set to allow for exposure of the film in several strips, thus eliminating the parallax error caused by the cone-shaped radiation field and creating a higher resolution radiograph. The results show that an IMRS is a fast and reliable means for inspecting large aircraft surfaces. Inspection of helicopter rotor blades for water ingress in honeycomb is seen as one possible use for the IMRS, expecially for very large blades. In-motion radiography is simple and based on standard radiographic procedures, with some slight modifications in exposure settings. Almost any radiography system could be adapted to use in-motion radiography if the tube or the part is able to move in the desired scanning motion. In-house testing of the IMRS is complete and ready for an on-aircraft trial. Author (CISTI)

INVESTIGATION OF THE BOND STRENGTH OF A DISCRETE SKIN-STIFFENER INTERFACE
H. G. S. J. Thuis and J. F. M. Wiggenraad 24 Apr. 1992 14 p Presented at the AGARD/SMP Specialists Meeting on Debonding/Delamination of Composites, Patras, Greece, 25-27 May 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NLR-TP-92183-U; ETN-94-95446) Avail: CASI HC A03

The results of an experimental study on the effects of several design parameters on the strength of a skin-stiffener interface are presented. Design parameters considered are skin and stiffener laminate properties and the width of the bond layer. Test specimens consisting of a blade type stiffener secondarily bonded to skin laminate were fabricated. The specimens were tested by lateral tension tests, four point bending tests, and pull-off tests. Calculations were made with the numerical program BONDST. The test results are compared with each other and with the calculated results. Conclusions are drawn and design guidelines are provided. ESA

EXAMPLES OF FLIGHT PATH OPTIMISATION USING A MULTIVARIATE GRADIENT-SEARCH METHOD
Dec. 1993 24 p
(ISSN 0141-4054)
(ESDU-93021; ISBN-0-85679-874-6) Avail: ESDU

ESDU 93021 deals with one method of optimization of a complete sortie, applied as an example to a subsonic transport and used to demonstrate the penalties incurred by constraints imposed by design and operational considerations. It requires an appropriate numerical optimization technique able to solve constrained multivariate problems. That used here is RQPMIN developed at the then Royal Aircraft Establishment. The examples were to minimize block fuel for given range, maximize range for given ramp mass, minimize time for given range, and minimize direct operating costs (in this case a linear combination of time and block fuel) for given range. Each case is initially run with no constraints other than those to ensure flight is possible (for example, thrust at the appropriate rating must exceed drag). Progressive constraints are then introduced relating speed to minimum drag speed, providing a given margin to buffet onset, limiting rates of climb and descent by rates of cabin pressure change and by a maximum cabin differential pressure, and limiting cabin attitude for passenger comfort. The results are discussed. A comparison is also made of results for optimum climb paths of a transport aircraft with results obtained for the same cases in ESDU 90012 using energy height methods. EXAMPLE OF STATISTICAL TECHNIQUES APPLIED TO ANALYSIS OF EFFECTS OF SMALL CHANGES
Nov. 1993 6 p
(ISSN 0141-4054)
(ESDU-93023; ISBN-0-85679-876-2) Avail: ESDU

ESDU 93023 uses second segment climb measurements to provide simple examples of statistical significance testing and confidence levels. Certification trials of a twin turbo-prop aircraft established that second segment climb gradient exceeded scheduled by a mean margin of 0.09 percent with a standard deviation of 0.35 percent. The comprehensive nature of the tests allowed the values to be taken as applying to the population. Two sets of ten points were then obtained, each set with a variant of the aircraft differing from the basic design by small aerodynamic changes. Use of Fisher's Variance Ratio F test established that the standard deviations (variances) of both sets did not differ significantly from that of the population. The means of both samples were then compared with that of the population using the normal cumulative distribution function to establish the confidence that the differences arose by chance. In one case the difference is seen to be significant and the performance had to be rescheduled. The necessary changes are calculated, and the probability that any single test point might fall below the new scheduled level is established. ESDU

WEAPON SYSTEM SENSOR INTEGRATION FOR A DIS-COMPATIBLE VIRTUAL COCKPIT M.S. Thesis
Matthew N. Erichsen Dec. 1993 153 p
(AD-A274088; AFIT/GCS/Eng/93-07) Avail: CASI HC A08/MF A02

This thesis continues the virtual cockpit (VC) research which investigates distributed interactive virtual flying environments. The VC v1.0 used the SIMNET protocols to only communicate position and orientation over a common network. A simple cockpit instrumentation configuration and limited head-up display (HUD) showed aircraft state. With VC v1.0, weapons or sensors could not interact in the simulation environment. The VC v2.0 transitions from the SIMNET protocol to a partial implementation of the Distributed Interactive Simulation (DIS) v2.0.3 protocol. Simulated radar and forward looking infrared (FLIR) sensors were developed to aid operator detection and designation when employing various munition types. Simulated munition types include: radar or IR missiles; free-fall, laser guided, or electro-optic (EO) guided bombs; and a 20mm cannon. Virtual environments were created with CRT out-the-window presentations, color NTSC and monochrome high-resolution helmet mounted displays employing Polhemus head tracking sensors, and simultaneously five-channels on BARCO projectors. Target graphics systems included SGI workstations with Onyx processors using Reality Engines. Graphics rendering was accomplished with an AFIT developed object oriented simulation software package based on the SGI Performer 1.2 application development environment. DTIC

DIGITAL SYSTEMS VALIDATION BOOK PLAN. VOLUME 3: HANDBOOK Final Report
Joan Janowitz Jul. 1993 17 p
(Contract DTFA03-89-C-00043)
(AD-A274099; DOT/FAA/CT-93/16-Vol-3) Avail: CASI HC A03/MF A01

The Digital Systems Validation Handbook is a tutorial series designed to provide certification engineers information on current topics related to digital avionics. The book plan lays the foundation for volume three of this series. The purpose of the handbook book plan is to identify technology and related issues that certification engineers are likely to encounter. Volume three of the handbook series will consist of approximately 20 chapters. Sixteen chapters are described in the book plan. Four were reserved for technologies or issues that might emerge during the course of the volume three life cycle. A list of potential handbook topics was derived from a survey of the literature, conference and seminar attendance, results of an informal questionnaire, and interviews with Federal Aviation Administration (FAA) National Resource Specialists, experts in the field of certification and digital avionics, National Aeronautics and Space Administration (NASA) officials, and persons in private industry. From this input, the list of potential topics was developed and refined into handbook chapters. In addition to the chapter list and descriptions, the handbook purpose, scope, and use is discussed. The unabridged list of topics is included in the book plan appendix. DTIC

DIGITAL ALTIMETER SETTING INDICATOR (DASI) OPERATIONAL TEST AND EVALUATION (OT/E) OPERATIONAL TEST PROCEDURES
Michael Greco, Paul Biagi, and Eric Hoover Dec. 1993 35 p
(AD-A274100; DOT/FAA/CT-TN93/44) Avail: CASI HC A03/MF A01

The Digital Altimeter Setting Indicator (DASI) is a system which measures the atmospheric pressure and converts the measured pressure value into the actual sea level pressure based on the United States (U.S.) Standard Atmospheric Table. The value then computed is known as the altimeter setting indicator (ASI) value and is presented to an air traffic controller, in a digital format, e.g., 29.50 inches of mercury. The ASI value is then transmitted by the air traffic controller to an aircraft pilot for use in setting the altimeter in the aircraft. If a perfectly calibrated altimeter is set to the ASI value existing at any given station whose elevation is designated as Hp, the pointer of the altimeter instrument will indicate an altitude of Hp when the instrument is at the altitude of the sensor in the DASI system. Hp is an elevation in geopotential meters above mean sea level of the altimeter setting indicator pressure sensor. The purpose of this operational test and evaluation (OT&E) test procedure is to describe the test and evaluation activities which will ensure the DASI system meets all the requirements of the DASI Specification, FAA-E-2569B, and integrates properly into the National Airspace System (NAS). The OT&E procedure includes the test cases, responsibilities, test support hardware and software, and test conduct associated with the testing of the DASI. The DASI test is developed and executed in accordance with the current FAA Test and Evaluation Policy Order, FAA Order 1810.4B. DTIC

COLOR HEAD DOWN DISPLAY PROGRAM Final Report, 1 Sep. 1988 - 1 Mar. 1993
D. L. Jose, A. C. Ipri, and R. G. Stewart Apr. 1993 66 p
(Contract F33615-88-C-1825)
(AD-A274807; WL-TR-93-1103) Avail: CASI HC A04/MF A01

The purpose of the CHDD program was to develop a large-area AMLCD for cockpit applications. A 4- x 8-in. polysilicon AMLCD with 320,000 display cells was designed with integrated scanners and fabricated. A support electronics system was constructed that accepted multisource RGB video. This system reformatted the video information to drive the display at 180 fields/second and synchronized the display to a color sequential backlight. Moving the color information into the temporal domain, maintained the color pixel density identical to the cell density. A 192 x 192 pixel active matrix circuit with integrated drive and scan functions was fabricated in thin-film single-crystal silicon, using standard IC processing, and subsequently placed on glass to form a transmissive AMLCD. The first assembled 2.5- x 2.5-in. monochrome display shows greater than 85 percent pixel functionality. The speed, low leakage current, and high drive capability of single-crystal silicon devices should allow the fabrication of displays with integrated system-level peripheral circuitry, high pixel density, and improved contrast and optical aperture ratios. Researchers and pilots throughout the world continue to examine and debate the utility of the head-up display (HUD) for presenting instrument flight information. Although initially intended for the presentation of landing and weapons delivery information, the HUD has evolved into a flight instrument that researchers and pilots claim is successfully replacing many of the traditional panel instruments. Since the Attitude Awareness Workshop of 1985, the United States Air Force (USAF) has conducted numerous research projects to determine the most effective way to integrate the HUD with the other mission-essential instrument displays. The requirement to use the HUD for instrument flight, as well as a need to determine the optimal configuration of the HUD symbols, prompted a significant portion of that research. The research efforts conducted by scientists in the Visual Orientation Laboratory (VOL) and the Flight Motion Effects Branch of the Armstrong Laboratory (AL/CFTF) are summarized. Suggested standardization guidelines based on empirical findings are discussed, including the use of: counter-pointers for airspeed and altitude indicators, vertical and horizontal asymmetry for pitch-ladder configurations, a ghost horizon, analog information for vertical velocity, energy management symbology, and quickening for climb/dive markers. In the aviation community, the early detection of the development of a possible subsystem problem during a flight is potentially useful for increasing the safety of the flight. Commercial airlines are currently using twin-engine aircraft for extended transport operations over water, and the early detection of a possible problem might increase the flight crew's options for safely landing the aircraft. One method for decreasing the severity of a developing problem is to predict the behavior of the problem so that appropriate corrective actions can be taken. To investigate the pilots' ability to predict long-term events, a computer workstation experiment was conducted in which 18 airline pilots predicted the alert time (the time to an alert) using 3 different dial displays and 3 different parameter behavior complexity levels. The three dial displays were as follows: standard (resembling current aircraft round dial presentations); history (indicating the current value plus the value of the parameter 5 sec in the past); and predictive (indicating the current value plus the value of the parameter 5 sec into the future). The time profiles describing the behavior of the parameter consisted of constant rate-of-change profiles, decelerating profiles, and accelerating-then-decelerating profiles. Although the pilots indicated that they preferred the near term predictive dial, the objective data did not support its use. The objective data did show that the time profiles had the most significant effect on performance in estimating the time to an alert. Author (revised)

EFFECTS OF EXPECTED-VALUE INFORMATION AND DISPLAY FORMAT ON RECOGNITION OF AIRCRAFT SUBSYSTEM ABNORMALITIES
Michael T. Palmer and Kathy H. Abbott Mar. 1994 76 p
(RTOP 505-64-13-22)
(NASA-TP-3395; L-17262; NAS 1.60:3395) Avail: CASI HC A05/MF A01

This study identifies improved methods to present system parameter information for detecting abnormal conditions and to identify system status. Two workstation experiments were conducted. The first experiment determined if including expected-value-range information in traditional parameter display formats affected subject performance. The second experiment determined if using a nontraditional parameter display format, which presented relative deviation from expected value, was better than traditional formats with expected-value ranges included. The inclusion of expected-value-range information onto traditional parameter formats was found to have essentially no effect. However, subjective results indicated support for including this information. The nontraditional column deviation parameter display format resulted in significantly fewer errors compared with traditional formats with expected-value-ranges included. In addition, error rates for the column deviation parameter display format remained stable as the scenario complexity increased, whereas error rates for the traditional parameter display formats with expected-value ranges increased. Subjective results also indicated that the subjects preferred this new format and thought that their performance was better with it. The column deviation parameter display format is recommended for display applications that require rapid recognition of out-of-tolerance conditions, especially for a large number of parameters. DEVELOPMENT AND IMPLEMENTATION OF A SCRAMJET CYCLE ANALYSIS CODE WITH A FINITE-RATE-CHEMISTRY COMBUSTION MODEL FOR USE ON A PERSONAL COMPUTER M.S. Thesis
Clarence F. Chenault Dec. 1993 254 p
(AD-A273834; AFIT/GAE/ENY/93D-7) Avail: CASI HC A12/MF A03

This study compared the performance of an equilibrium combustion model to a finite-rate-chemistry combustion model for a fixed geometry scramjet flying at the flight conditions of Mach 12, 15, and 18 with a constant dynamic pressure of 50,000 Pa. An integrated PC-based code, developed specifically for this study, models the combustor as an equilibrium combustion process or as finite-rate-chemistry combustion process. This integrated program is based on two existing programs, Ramjet Performance Analysis (RJPA) and 3 STREAM. The effects of mixing schedule, combustor length, and combustor exit area were investigated. The results of this study indicate that inefficient mixing is the primary cause of Scramjet performance loss regardless of the flight speed. Combustor length and combustor exit area also had a strong impact on performance. DTIC

AIRCRAFT TURBINE ENGINE RELIABILITY AND INSPECTION INVESTIGATIONS Final Report

Bruce A. Richter, Margaret Ridenour-Bender, and Mike Tsao Oct. 1993 120 p Sponsored by FAA
(AD-A274860; SAIC-67-6733; DOT/FAA/CT-92/29) Avail: CASI HC A06/MF A02

This study of JT9D, CF6, and PT6 aircraft engine reliability represents a follow-on effort to the JT8D engine study which was published in the Federal Aviation Administration (FAA) Technical Center Final Report DOT/FAA/CT-91/10. As with the JT8D engine study, this study trended in-flight shutdowns and unscheduled removal rates of JT9D, CF6, and PT6 turbine aircraft engines for a thirty-six-month period covering February 1988 through January 1991. As in the previous report, the methodology was to review which air carriers consistently exceeded the standard deviation norm for in-flight shutdowns and unscheduled engine removals on a monthly basis and then examine the engine component failures reported by those carriers. Engine component failures were grouped as follows: bearings, airfoils, cases, controls and accessories, fuel/oil systems, and others (not trended). For this study of the JT9D, CF6, and PT6 engines, controls and accessories typically produced the largest number of in-flight flameouts, compressor stalls, and engine shutdowns. In addition to the actuarial analysis and component failure mode trending performed on the JT9D, CF6, and PT6 engines, application of an inspection procedure developed for the JT8D engine was made on the JT9D and CF6 engine cases. AN INVESTIGATION OF THE SURGE BEHAVIOR OF A HIGH-SPEED TEN-STAGE AXIAL FLOW COMPRESSOR Final Report, Aug. 1990 - Aug. 1992
Patrick Russler May 1993 162 p
(AF Proj. 3066)
(AD-A274910; WL-TR-93-2076) Avail: CASI HC A08/MF A02

During a ten-stage compressor rig test conducted at Wright-Patterson AFB, several instances of compressor surge were observed. While surge is known to occur in high-speed multi-stage compressors, very little transient data pertaining to such events exists in the open literature, exclusive of engine data. In an attempt to make more data of this type available to researchers, surge data from this test are presented in this report. The predictions of a computer-based transient compressor model are compared to the data for study. Furthermore, an unexplained instability phenomenon is investigated: a constant surge/rotating stall boundary. During the test, it was found that the speed boundary between surge and rotating stall occurred between 80% and 81% rotor speed. This boundary did not change when the compressor discharge volume was changed. This seemed to contradict accepted theory, which predicts a shift in the surge/rotating stall boundary. An investigation into the possible causes of this phenomenon is conducted as part of this report. Several theories are explored, including the possibility of excess volume communicating with the compressor during instability. Although the excess volume theory is not proven, it remains the most likely cause of the unusual surge/rotating stall boundary behavior. DTIC

Multiple venturi fuel injectors were used to obtain uniform fuel distributions, better atomization and vaporization in the premixing/prevaporizing section of a lean premixed/prevaporized flame tube combustor. A focused Schlieren system was used to investigate the fuel/air mixing effectiveness of various fuel injection configurations. The Schlieren system was focused to a plane within the flow field of a test section equipped with optical windows. The focused image plane was parallel to the axial direction of the flow and normal to the optical axis. Images from that focused plane, formed by refracted light due to density gradients within the flow field, were filmed with a high-speed movie camera at framing rates of 8,000 frames per second (fps). Three fuel injection concepts were investigated by taking high-speed movies of the mixture flows at various operating conditions. The inlet air temperature was varied from 600 F to 1000 F, and inlet pressures from 80 psia to 150 psia. Jet-A fuel was used typically at an equivalence ratio of 0.5. The intensity variations of the digitized Schlieren images were analytically correlated to spatial density gradients of the mixture flows. Qualitative measurements for degree of mixedness, intensity of mixing, and mixing completion time are shown. Various mixing performance patterns are presented with different configurations of fuel injection points and operating conditions. Author (revised)

Flows in low-aspect ratio turbines, such as the SSME fuel turbine, are three dimensional and highly unsteady due to the relative motion of adjacent airfoil rows and the circumferential and spanwise gradients in total pressure and temperature, The systems used to design these machines, however, are based on the assumption that the flow is steady. The codes utilized in these design systems are calibrated against turbine rig and engine data through the use of empirical correlations and experience factors. For high aspect ratio turbines, these codes yield reasonably accurate estimates of flow and temperature distributions. However, future design trends will see lower aspect ratio (reduced number of parts) and higher inlet temperature which will result in increased three dimensionality and flow unsteadiness in turbines. Analysis of recently acquired data indicate that temperature streaks and secondary flows generated in combustors and up-stream airfoils can have a large impact on the time-averaged temperature and angle distributions in downstream airfoil rows. SIMULATING INDIRECT THRUST MEASUREMENT METHODS AS USED ON MODERN HIGH-BYPASS TURBOFANS M.S. Thesis
Jonathan David Stevenson Dec. 1992 143 p
(ISBN-0-315-84123-0; CTN-94-61059) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

As yet, there is no known reliable method for directly measuring the thrust of a turbofan in flight. Manufacturers of civil turbofans use various indirect thrust measurements to indicate performance of an engine to the flight deck. Included among these are engine pressure ratio (EPR), integrated engine pressure ratio (IEPR), fan mechanical speed as a percentage of its design speed (N1), and various turbine gas temperatures. Of key concern is whether these thrust indicators give an accurate account of the actual engine thrust. A study was undertaken to determine the effect of advanced engine cycles on typical values of the most popular thrust setting parameters, using a generic computer model of a twin-spool high bypass ratio turbofan. A preliminary investigation was conducted to determine the effects of various kinds of engine deterioration on the engine performance and the indirect thrust indicators. The results show very little difference between the most popular thrust indicator methods used. EPR and IEPR have the unique advantage of being self-correcting to a wide range of ambient takeoff temperatures, but are affected by changes in altitude, forward speed, and engine cycle. N1 appears to exhibit different behavior at takeoff and cruise operation, but has the advantage of being intuitive to pilots. Author (CISTI)

This report describes the design, development and flight testing of the

Propulsion Controlled Aircraft (PCA) flight control system performed at McDonnell Douglas Aerospace (MDA), St. Louis, Missouri and at the NASA Dryden Flight Research Facility, Edwards Air Force Base, California. This research and development program was conducted by MDA and directed by NASA through the Dryden Flight Research Facility for the period beginning January 1991 and ending December 1993. A propulsion steering backup to the aircraft conventional flight control system has been developed and flight demonstrated on a NASA F-15 test aircraft. The Propulsion Controlled Aircraft (PCA) flight system utilizes collective and differential thrust changes to steer an aircraft that experiences partial or complete failure of the hydraulically actuated control surfaces. The PCA flight control research has shown that propulsion steering is a viable backup flight control mode and can assist the pilot in safe landing recovery of a fighter aircraft that has damage to or loss of the flight control surfaces. NASA, USAF and Navy evaluation test pilots stated that the F-15 PCA design provided the control necessary to land the aircraft. Moreover, the feasibility study showed that PCA technology can be directly applied to transport aircraft and provide a major improvement in the survivability of passengers and crew of controls damaged aircraft. EXPERIMENTAL AND THEORETICAL INVESTIGATIONS OF THE INFLUENCE OF THE JET ON THE FLOW AROUND A BYPASS-ENGINE [EXPERIMENTELLE UND THEORETISCHE UNTERSUCHUNGEN UEBER DEN STRAHLEINFLUSS BEI DER UMSTROEMUNG EINES BYPASS-TRIEBWERKES]

Andreas Korus Dec. 1992 130 p In GERMAN
(ISSN 0939-2963)
(DLR-FB-93-17; ETN-94-95495) Avail: CASI HC A07/MF A02

The characteristics of jet flows and their interference with boat tails are described, and experimental investigations with a 'hot jet simulator' of the bypass engine CF6-50 on the 'jet simulation tunnel' are described. The influences of the nozzle pressure ratios and the free stream Mach number on the pressure distributions of the engine contours and the jet behavior, as well as the mutual effects on the fan and core jet are investigated, due to measurements with a cold core jet. Subsequently, the results of the jets on the flow around the bypass engine carried out theoretically using the coupled STC (Stream Tube Curvature)-GENMIX code. An Euler code was used to examine the influence of the shape of the jet profile on the pressure distribution of the core cowl contour. The results received from the measurements and the calculations were compared. ESA

(ISSN 0389-4010)
(NAL-TR-1187T; JTN-94-80615) Avail: CASI HC A03/MF A01

Heating tests and analysis of a cooling panel that simulates the leading edge of a scramjet engine inlet or strut were performed using a crossflow type water-cooled panel with a circular leading edge. The cooling panel was fabricated by nickel electroforming and heated by supersonic hot gas. An NTO (Nitrogen TetraOxide) and MMH (MonoMethyl Hydrazine) rectangular chamber was used as the gas generator. The free stream Mach number at the nozzle exit was about 2.67. Water was used as the coolant, and heat flux distribution was measured based on the temperature increase. Thermal analyses were performed using a two-dimensional CFD (Computational Fluid Dynamics) code and a finite element code. The results of the analysis were compared with the experimental data. PREDICTION OF UNDSTEADY FLOWS IN TURBOMACHINERY USING THE LINEARIZED EULER EQUATIONS ON DEFORMING GRIDS Final Report

William S. Clark and Kenneth C. Hall Mar. 1994 111 p
(Grant NAG3-1192; RTOP 505-62-10)
(NASA-CR-195285; E-8630; NAS 1.26:195285) Avail: CASI HC A06/MF A02

A linearized Euler solver for calculating unsteady flows in turbomachinery blade rows due to both incident gusts and blade motion is presented. The model accounts for blade loading, blade geometry, shock motion, and wake motion. Assuming that the unsteadiness in the flow is small relative to the nonlinear mean solution, the unsteady Euler equations can be linearized about the mean flow. This yields a set of linear variable coefficient equations that describe the small amplitude harmonic motion of the fluid. These linear equations are then discretized on a computational grid and solved using standard numerical techniques. For transonic flows, however, one must use a linear discretization which is a conservative linearization of the non-linear discretized Euler equations to ensure that shock impulse loads are accurately captured. Other important features of this analysis include a continuously deforming grid which eliminates extrapolation errors and hence, increases accuracy, and a new numerically exact, nonreflecting far-field boundary condition treatment based on an eigenanalysis of the discretized equations. Computational results are presented which demonstrate the computational accuracy and efficiency of the method and demonstrate the effectiveness of the deforming grid, far-field nonreflecting boundary conditions, and shock capturing techniques. A comparison of the present unsteady flow predictions to other numerical, semi-analytical, and experimental methods shows excellent agreement. In addition, the linearized Euler method presented requires one or two orders-of-magnitude less computational time than traditional time marching techniques making the present method a viable design tool for aeroelastic analyses. THE DESIGN OF A COUNTER ROTATING ULTRA-HIGH-BYPASS FAN SIMULATOR FOR WINDTUNNEL INVESTIGATION [AUSLEGUNG EINES COUNTER ROTATING ULTRA-HIGH-BYPASS FAN SIMULATORS FUER WINDKANALUNTERSUCHUNGEN]

Heinz Hoheisel Mar. 1993 84 p Original contains color illustrations
(ISSN 0939-2963)
(DLR-FB-93-20; ETN-94-95497) Avail: CASI HC A05/MF A01

The procedure and special aspects that had to be taken into account during the design of an engine simulator to be used for simulating the integration of airframes and engines with ultra high bypass ratios are described. The simulator should be able to simulate the aerodynamics and acoustics of the real engine. For this reason, the simulator was designed with a counter rotating fan. The counter rotation of the fan was generated by a reverse gearbox, similar to the real engine where a gearbox is necessary to maintain a good LP turbine efficiency. ESA

COUPLED 2-DIMENSIONAL CASCADE THEORY FOR NOISE AN D UNSTEADY AERODYNAMICS OF BLADE ROW INTERACTION IN TURBOFANS. VOLUME 2: DOCUMENTATION FOR COMPUTER CODE CUP2D

Donald B. Hanson Washington Jan. 1994 42 p
(Contract NAS3-25952; RTOP 535-03-10)
(NASA-CR-4506-Vol-2; E-7766; NAS 1.26:4506-Vol-2) Avail: CASI HC A03/MF A01

A two dimensional linear aeroacoustic theory for rotor/stator interaction with unsteady coupling was derived and explored in Volume 1 of this report. Computer program CUP2D has been written in FORTRAN embodying the theoretical equations. This volume (Volume 2) describes the structure of the code, installation and running, preparation of the input file, and interpretation of the output. A sample case is provided with printouts of the input and output. The source code is included with comments linking it closely to the theoretical equations in Volume 1. Author (revised)

THE APPLICATION OF A C(STAR) FLIGHT CONTROL LAW TO LARGE CIVIL TRANSPORT AIRCRAFT Ph.D. Thesis
Edmund Field Mar. 1993 45 p Sponsored by United Kingdom Science and Engineering Research Council
(Cranfield-Aero-9303; ISBN-1-871564-58-1; ETN-94-95222) Avail: CASI HC A03/MF A01

The aim of the program is to design flight control laws to give fly by wire civil transport aircraft excellent flying qualities at all flight conditions. The most critical flight phase of a civil transport is the landing approach. An analysis of the C(star) parameter is presented. The C(star) criterion was one of the first handling qualities criteria designed to take account of advanced aerodynamic designs of modern aircraft and higher order systems introduced by flight control systems. Several aircraft have since employed control laws based around the C(star) parameter. A proportional feedback C(star) controller was applied to a Boeing 747-100 in landing approach configuration, and assessed against the C(star) criterion. ESA

DESIGN OF A SUBSONIC ENVELOPE FLIGHT CONTROL SYSTEM FOR THE VISTA F-16 USING QUANTITATIVE FEEDBACK THEORY M.S. Thesis
Odell R. Reynolds Dec. 1993 180 p
(AD-A274057; AFIT/GE/Eng/93D-34) Avail: CASI HC A09/MF A02

A controlled plant's characteristics can vary widely throughout its operational envelope. This is a major problem in nominal plant-based control system design. Hence, gain scheduling is often used for full envelop design. In this paper, it is proposed to address the plant's variability using robust control design concepts. In particular, the frequency domain based Quantitative Feedback Theory Multiple-Input Multiple-Output robust control design method is employed for the synthesis of a full envelop flight control system for an F-16 derivative. Compensators for the aircraft's pitch and lateral directional channels are designed, and the designs are validated using linear simulations. DTIC

NEURAL NETWORKS FOR DYNAMIC FLIGHT CONTROL M.S. Thesis
Ronald E. Setzer Dec. 1993 140 p
(AD-A274089; AFIT/GE/Eng/93D-36) Avail: CASI HC A07/MF A02

This thesis examines the application of artificial neural networks (NN's) to the problem of dynamic flight control. The specific application is the control of a flying model helicopter. The control interface is provided through a hardware and software test bed called the Fast Adaptive Maneuvering Experiment (FAME). The NN design approach uses two NN's: one trained as an emulator of the plant and the other trained to control the emulator. The emulator neural network is designed to reproduce the flight dynamics of the experimental plant. The controller is then designed to produce the appropriate control inputs to drive the emulator to a desired final state. Previous research in the area of NN's for controls has almost exclusively been applied to simulations. To develop a controller for a real plant, a neural network must be created which will accurately recreate the dynamics of the plant. This thesis demonstrates the ability of a neural network to emulate a real, dynamic, nonlinear plant. DTIC

DESIGN OF A FLIGHT CONTROLLER FOR AN UNMANNED RESEARCH VEHICLE WITH CONTROL SURFACE FAILURES USING QUANTITATIVE FEEDBACK THEORY M.S. Thesis

Mark S. Keating Dec. 1993 163 p

(AD-A274049; AFIT/GE/Eng/93D-18) Avail: CASI HC A08/MF A02

This thesis describes the application of the multiple-input multiple-output (MIMO) Quantitative Feedback Theory (QFT) design technique to the design of a digital flight control system for the Lambda Unmanned Research Vehicle (URV). The QFT technique allows the synthesis of a control system which is robust in the presence of structured plant uncertainties. Uncertainties considered in this design are the aircraft's plant variation within the flight envelope and the effects of damage to aircraft control surfaces. Mathematical models of control surface failure effects on aircraft dynamics are derived and used to modify an existing small perturbation model of the Lambda. The QFT technique is applied to design a control system utilizing aircraft pitch rate, roll rate and sideslip angle as feedback variables. The inherent cross-coupling rejection qualities of QFT and an aileron-rudder interconnect are utilized to design a control system which results in a coordinated flight. An outer-loop autopilot is then designed around the QFT controller to further assist turn coordination. Sensor noise effects on aircraft states are also analyzed. DTIC

DISCOVERY LEARNING IN AUTONOMOUS AGENTS USING GENETIC ALGORITHMS M.S. Thesis

Edward O. Gordon Dec. 1993 209 p

(AD-A274083; AFIT/GE-93D-10) Avail: CASI HC A10/MF A03

As the new Distributed Interactive Simulation (DIS) draft standard evolves into a useful document and distributed simulations begin to emerge that implement parts of the standard, there is renewed interest in available methods to effectively control autonomous aircraft agents in such a simulated environment. This investigation examines the use of a genetics-based classifier system for agent control. These are robust learning systems that use the adaptive search mechanisms of genetic algorithms to guide the learning system in forming new concepts (decision rules) about its environment. By allowing the rule base to evolve, it adapts agent behavior to environmental changes. Addressed are the learning needs of autonomous aircraft agents, showing how multiple learning strategies are possible and that the best approach is a coherent combination of these. A design is described for a control system using a distributed filtering architecture and a genetics-based classifier system modified to support a phasing-rule niching system based on phase tags. Finally, a prototype system called the Phased Pilot Learning System (PPLS) is implemented based on this design and tested within a limited simulation environment. Results from empirical tests show that this approach is a viable alternative to other control methods. DTIC

LINEAR MODELING OF ROTORCRAFT FOR STABILITY ANALYSIS AND PRELIMINARY DESIGN M.S. Thesis

Walter M. Wirth, Jr. Sep. 1993 188 p

(AD-A274869) Avail: CASI HC A09/MF A02

This thesis investigates linear state space modeling of single main rotor helicopters culminating in a computer program that can be used for stability and control analysis for any single main rotor helicopter or preliminary design of a helicopter. The trim solution for a flight condition is found, the aircraft is perturbed about the nominal point, and the stability and control derivatives are determined. State space models and analysis tools are provided by the program. A notional attack helicopter designed for the 1993 American Helicopter Society Design Competition and a notional utility helicopter are used as examples. DTIC

THE RELATIONSHIP OF AN INTEGRAL WIND SHEAR HAZARD TO AIRCRAFT PERFORMANCE LIMITATIONS

M. S. Lewis, P. A. Robinson, D. A. Hinton, and R. L. Bowles Feb. 1994 18 p

(RTOP 505-64-12-01)

(NASA-TM-109080; NAS 1.15:109080) Avail: CASI HC A03/MF A01

The development and certification of airborne forward-looking wind shear detection systems has required a hazard definition stated in terms of sensor observable wind field characteristics. This paper outlines the definition of the F-factor wind shear hazard index and an average F-factor quantity, calculated over a specified averaging interval, which may be used to judge an aircraft's potential performance loss due to a given wind shear field. A technique for estimating airplane energy changes during a wind shear encounter is presented and used to determine the wind shear intensity, as a function of the averaging interval, that presents significant hazard to transport category airplanes. The wind shear hazard levels are compared to averaged F-factor values at various averaging intervals for four actual wind shear encounters. Results indicate that averaging intervals of about one kilometer could be used in a simple method to discern hazardous shears. Author (revised)

AN ADAPTIVE KALMAN FILTER FOR TACTICAL MISSILES GUIDANCE SYSTEMS M.S. Thesis

Jingming Li 15 Jan. 1993 142 p

(ISBN-0-315-84115-X; CTN-94-61055) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The Kalman filter can be used to upgrade inertial navigation systems (INS's) without costly upgrading of the hardware. Current methods of integrating Kalman filters into INS's are investigated. A standard Kalman filter algorithm is implemented in the INS for a glide weapon system in order to assess the performance of the filter. An adaptive Kalman filter is then implemented to illustrate the performance improvement. The Kalman filter estimates the navigation error in real time with the aid of other external signal sources. The INS receives these signals and makes appropriate compensations. The estimation results from the standard Kalman filter may diverge from the actual error signal either because of the changing dynamics or inaccurate parameters. The adaptive Kalman filter could tune itself to work within the new environment. A Kalman filter convergent criterion and an on-line noise covariance estimation algorithm are described. An approach that combines the S Kalman filter and on-line variable indentifications is suggested. Simulation results for the standard and adaptive Kalman filters are discussed and compared. THE EFFECTS OF TAILWINDS AND CONTROL CROSS COUPLING ON ROTORCRAFT HANDLING QUALITIES FOR STEEP, DECELERATING INSTRUMENT APPROACHES AND MISSED APPROACHES

S. W. Baillie, S. Kereliuk, and J. M. Morgan Sep. 1993 72 p

(IAR-AN-77; NRC-32159; CTN-94-61007) Avail: CASI HC A04/MF A01

The expansion of the rotorcraft instrument flight envelope to allow steep, decelerating approaches to low speeds and altitudes will profoundly improve the utility of those vehicles. As a supplement to previously published investigations, a research program was conducted using the Bell 205 Airborne Simulator, whose results provide a data base on which rotorcraft instrument flight certification standards can be formulated for rotorcraft operations equivalent to Category III A. The research was conducted to document the effect of conducting steep, decelerating approaches in the presence of tailwinds. The handling qualities factors of terminating the approach with one of three missed approach procedures were investigated, and the height loss at the initiation of a missed approach procedure was documented. The handling qualities degradation induced by inter-axis control cross coupling was also assessed. The handling qualities and performance were found to be acceptable at speeds down to 10 knots when approaches were performed with a tailwind present. The initiation of missed approach procedures resulted in minimum altitudes that approached 20 feet in some cases. Increased levels of inter-axis control cross coupling had little effect on handling qualities on approach. CISTI

RESEARCH IN ROBUST CONTROL FOR HYPERSONIC AIRCRAFT Progress Report No. 3, 1 Sep. 1993 - 28 Feb. 1994

A. J. Calise Mar. 1994 27 p
(Grant NAG1-1451)
(NASA-CR-195250; NAS 1.26:195250) Avail: CASI HC A03/MF A01

The research during the third reporting period focused on fixed order robust control design for hypersonic vehicles. A new technique was developed to synthesize fixed order H(sub infinity) controllers. A controller canonical form is imposed on the compensator structure and a homotopy algorithm is employed to perform the controller design. Various reduced order controllers are designed for a simplified version of the hypersonic vehicle model used in our previous studies to demonstrate the capabilities of the code. However, further work is needed to investigate the issue of numerical ill-conditioning for large order systems and to make the numerical approach more reliable. Author (revised)

FLUID DYNAMIC LINEAR ACCELEROMETER Patent Application

David E. Keyser, inventor (to Navy) 17 May 1993 16 p
(AD-D016042; US-Patent-Appl-SN-063844) Avail: CASI HC A03/MF A01

A linear acceleration sensing device operates through a fluid medium. A fluid signal output represents a differential pressure from the elastic deformation of a fluid-filled diaphragm or bellows assembly. A pair of fluid proximity sensors operate differentially in a fluid control network and detect the elastic deformation of the diaphragm assembly caused by increased hydrostatic pressure resulting from a change in acceleration, or g-force. AUTOMATION OF FORMATION FLIGHT CONTROL M.S. Thesis

Vincent P. Reyna 1994 193 p
(AD-A274137; AFIT/GE/Eng/94M-01) Avail: CASI HC A09/MF A03

The research contained in this thesis explores the concepts of Automated Formation Flight Control documented in three previous AFIT theses. The generic formation analyzed consists of a Leader and Wingman, with the Wingman referencing its maneuvers off of Leader maneuvers. Specifically, planar formation flight control concerning only heading and velocity changes is considered. Next, the vertical separation constraint is relaxed to allow wing maneuvers outside of the flight plane of the lead in order to minimize the energy expended by the wing in a maneuver. Analysis of the two forms of formation flight control investigated in this thesis reveals the close relationship between formation geometry, aircraft time constants, controller gains, formation performance, and control system stability. Integral control action is determined to be necessary for formation flight control. Nonlinear simulations are accomplished on a digital computer to validate the analysis of the automated formation flight control system. Comparisons are made between the two forms of formation flight control considered, and a third, energy conserving maneuvers, in order to determine which is best for each phase of flight. DTIC

OPTIMAL CONTROL OF HELICOPTERS FOLLOWING POWER FAILURE [HERIKOPUTA NO ENJIN KOSHOJI NO SAITEKI HIKO SEIGYO]

Yoshinori Okuno Jan. 1993 49 p In JAPANESE
(ISSN 0389-4010)
(NAL-TR-1190; JTN-94-80617) Avail: CASI HC A03/MF A01

Helicopter control procedures following power failure were theoretically investigated by applying nonlinear optimal control theory to the following four optimization problems: (1) Minimization of the touchdown speed following power failure. Comparisons between the calculated optimal solutions and the empirical flight test results showed that the pilots used nonoptimal controls, especially in the timing and amplitude of the collective flare before touchdown; (2) Prediction of the Height-Velocity (H-V) boundaries. The optimization problems were formulated to minimize the unsafe region under the condition that the touchdown speed is within the landing gear capacity. The calculated H-V boundaries showed good correlation with the flight test results. In addition, parameters such as the flight-path angle at the moment of power failure, collective control delay, collective setting during descent, landing site location and its available field length, and wind speed were found to have significant effects on the success of the emergency landing; (3) Optimization of the takeoff procedure for Category A STOL operation. The results show that the required takeoff distance using the normal takeoff procedure can be significantly reduced if the takeoff path and the critical decision point are specifically optimized for a given set of operating conditions, e.g., gross weight, ambient conditions, and heliport configuration; (4) Evaluation of the take-off performance for Category A VTOL operation. The calculated maximum weight when assuming the normal takeoff procedure showed good agreement with the certificated takeoff weight. Additionally, optimization of the takeoff path was shown to allow the payload to be increased. Author (NASDA)

THE DETERMINISTIC POWER-SPECTRAL-DENSITY METHOD

R. Noback 17 Mar. 1992 63 p Presented at Gust Specialists Meeting, Dallas, TX, 15 Apr. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract OV/RLD-132)
(AD-B175894; ETN-94-95443; NLR-TP-92114-U) Avail: CASI HC A04

The Deterministic Power Spectral Density (DPSD) method was derived directly from the continuous PSD method. It can be regarded as a 'translation' from the frequency domain to the space or time domain. The critical gust profile, giving maximum response, is obtained directly. The method was compared with the matched filter theory and with simulation. The DPSD method gives the same results as the continuous PSD method, for linear systems. The DPSD method was applied to a nonlinear system, using equivalent gain to obtain the critical gust profile. Results were compared with those obtained with simulation. ESA

COMPUTER CODE FOR CONTROLLER PARTITIONING WITH IFPC APPLICATION: A USER'S MANUAL Final Report

Phillip H. Schmidt and Asim Yarkhan Mar. 1994 76 p
(Grant NAG3-11467; RTOP 505-62-50)
(NASA-CR-195291; E-8654; NAS 1.26:195291) Avail: CASI HC A05/MF A01

A user's manual for the computer code for partitioning a centralized controller into decentralized subcontrollers with applicability to Integrated Flight/Propulsion Control (IFPC) is presented. Partitioning of a centralized controller into two subcontrollers is described and the algorithm on which the code is based is discussed. The algorithm uses parameter optimization of a cost function which is described. The major data structures and functions are described. Specific instructions are given. The user is led through an example of an IFCP application. Author (revised)

CONTROLLED OSCILLATION OF FOREBODY VORTICES BY NOZZLE JET BLOWING M.S. Thesis

Karim Alexan Dec. 1992 166 p
(ISBN-0-315-84134-6; CTN-94-61064) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The flowfield surrounding an ogive-cylinder type model immersed in a free stream fluid as its angle of attack is increased is discussed and the most promising methods of forebody vortex manipulation are reviewed. A scheme for controlling the behavior of forebody vortices at high angles of attack is experimentally investigated in a water tunnel at low speed. A detailed log of the repair work and modifications done to the water tunnel, a summary of operating procedures, and recommendations for its continued operation are provided. The use of port and starboard positioned, forward blowing nozzles located near the forebody apex is investigated. The ability of blowing to alter the orientation of asymmetrically positioned streamwise vortices is assessed and the possibility of using relatively rapid port-starboard oscillatory blowing to obtain a desired time-averaged side force and yaw moment is explored. The dynamic response of an F-18 aircraft to rapid oscillatory blowing at high angles of attack is approximated. The resulting amplitudes of oscillation indicate that this motion would likely be felt by the pilot but suggestions are made for improved performance of this oscillatory blowing system and for future research into oscillatory blowing for forebody vortex manipulation. TECHNIQUES TO IMPROVE MANEUVER STABILITY CHARACTERISTICS OF A NONLINEAR WIDE-BODY TRANSPORT AIRPLANE IN CRUISE FLIGHT
William D. Grantham, Lee H. Person, Jr., Melvin L. Bailey (Lockheed Engineering and Sciences Co., Hampton, VA.), and Stephen A. Tingas (Lockheed Aeronautical Systems Co., Marietta, GA.) Mar. 1994 66 p
(RTOP 505-64-52-01)
(NASA-TM-4521; L-17205; NAS 1.15:4521) Avail: CASI HC A04/MF A01

The maneuver control stability characteristics of an aircraft are a flying qualities parameter of critical importance, to ensure structural protection as well as adequate predictability to the pilot. Currently, however, maneuver stability characteristics are not uniquely addressed in the Federal Aviation Regulations (FAR) Part 25, for transport aircraft. In past transport category certification programs, the Federal Aviation Administration (FAA) has used a combination of requirements (longitudinal control, vibration and buffeting, high-speed characteristics, and out-of-trim characteristics) to ensure safe and controllable maneuver stability characteristics over a range of flight conditions and airplane configurations. Controversies exist regarding each of these regulations, however, and considerable expenditures in terms of design studies and testing time have resulted from the requirements. It is also recognized that additional engineering guidance is needed for identifying acceptable nonlinear maneuver stability characteristics, particularly as they relate to relaxed stability, highly augmented transport configurations. The current trend in large aircraft design is toward relaxed, or even negative, static margins for improved fuel efficiency. The advanced flight control systems developed for these aircraft, in many instances, have rendered current aforementioned maneuver stability criteria either too stringent or of little practical use. Current design requirements do not account for these advanced designs. The objective was to evaluate a broad spectrum of linear and nonlinear longitudinal stability characteristics to generate data for defining satisfactory and unacceptable maneuver characteristics, as defined by pilot opinion. Primary emphasis was placed on two techniques of varying column force per normal acceleration. This study was a joint venture with four pilots participating; one from NASA, one from the FAA, and two from industry. Author (revised)

UNDERSTANDING AND DEVELOPMENT OF A PREDICTION METHOD OF TRANSONIC LIMIT CYCLE OSCILLATION CHARACTERISTICS OF FIGHTER AIRCRAFT
Jos J. Meijer and Atlee M. Cunningham, Jr. 31 May 1992 17 p Presented at the 18th ICAS Congress, Beijing, China, 21-25 Sep. 1992; and AIAA Atmospheric Flight Mechanics Conference, Hilton Head, SC, 10-12 Aug. 1992 Sponsored by AF, General Dynamics Fort Worth, TX; Ministry of Defence, The Hague, Netherlands; and National Aerospace Lab., Amsterdam, Netherlands Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract NIVR-07801N)
(NLR-TP-92210-U; ETN-94-95448) Avail: CASI HC A03

An analysis of steady wind tunnel data, obtained for a fighter type aircraft, has indicated that shock induced and trailing edge separation play a dominant role in the development of limit cycle oscillations (LCO) at transonic speeds. On the basis of these data, a semiempirical LCO prediction method is being developed. Its preliminary version was applied to several configurations and correctly identified those which have encountered LCO. It has already shown the potential for application early in the design process of new aircraft to determine and understand the nonlinear aeroelastic characteristics. An upgraded form is described and results of the latest predictions are used to further assess various parametric effects. The ultimate refinements are expected from unsteady wind tunnel force and pressure measurements for which preliminary results are presented. ESA

DYNAMIC RESPONSE OF A COMPRESSOR RESEARCH FACILITY M.S. Thesis
Janet W. Grondin Dec. 1993 226 p
(AD-A273836; AFIT/GAE/ENY/93D-16) Avail: CASI HC A11/MF A03

The response of the Wright Laboratory Compressor Research Facility to a small amplitude, acoustic, sinusoidal disturbance was investigated. The fluid transmission line equations for laminar, one-dimensional flow in a circular duct were solved and verified through a laboratory experiment using a scale model of the facility. The resonant frequencies of the facility were determined for a variety of flow conditions. Techniques for analytically modeling end impedance and flow straightening elements were also studied. The fundamental frequency of the facility was determined to be between 5.5 and 6.5 Hz depending on the flow conditions and geometry configurations specified. DTIC

IMAGE QUALITY AND THE DISPLAY MODULATION TRANSFER FUNCTION: EXPERIMENTAL FINDINGS Final Report, Jan. 1991 - Mar. 1992
Ronald J. Evans Sep. 1993 89 p
(Contract F33615-90-C-0005)
(AD-A274061; AL/HR-TR-1993-0131) Avail: CASI HC A05/MF A01

Image quality metrics represent an attempt to quantify differences in the quality of the transmission and display of visual information. This report focuses on the components in the image transfer process which contribute to image quality as well as tasks through which image quality may be empirically defined. The components consist of the content of the original image, display device characteristics, and observer characteristics. Special attention within these three components is given to the display Modulation Transfer Function (MTF) which has traditionally been the major contributor to image quality metrics. Ambiguities exist in the definition and measurement of display MTF's and these problems are discussed as they pertain to image quality. Additional discussion includes the use of threshold versus suprathreshold tasks as empirical measures of image quality and the use of the Contract Sensitivity Function (CSF) versus the MTF of the eye in image quality metrics. An argument is presented which questions the use of either the CSF or MTF for suprathreshold tasks. In order to test the use of display MTF's in metrics, a methodology is described for digitally filtering images with filter representing hypothetical display MTF's. Although this method permits a subset of display MTF's to be compared, further efforts are requiredto compare MTF's which exhibit a crossover effect in the spatial frequency domain. Finally, empirical observations suggest that other display parameters (e.g., luminance) must be weighted more heavily in image quality metrics. DTIC

NASA LEWIS RESEARCH CENTER LEAN-, RICH-BURN MATERIALS TEST BURNER RIG Final Report
C. A. Stearns and R. C. Robinson Feb. 1994 58 p
(Contract NAS3-25266; RTOP 537-04-20)
(NASA-CR-194437; E-8285; NAS 1.26:194437) Avail: CASI HC A04/MF A01

The lean-, rich-burn materials test burner rig at NASA LeRC is used to evaluate the high temperature environmental durability of aerospace materials. The rig burns jet fuel and pressurized air, and sample materials can be subjected to both lean-burn and rich-burn environments. As part of NASA's Enabling Propulsion Materials (EPM) program, an existing rig was adapted to simulate the rich-burn quick-quench lean-burn (RQL) combustor concept which is being considered for the HSCT (high speed civil transport) aircraft. RQL materials requirements exceed that of current superalloys, thus ceramic matrix composites (CMC's) emerged as the leading candidate materials. The performance of these materials in the quasi reducing environment of the rich-burn section of the RQL is of fundamental importance to materials development. This rig was developed to conduct such studies, and its operation and capabilities are described. Author (revised)

MACHINE INTELLIGENT GUST FRONT ALGORITHM
Richard L. Delanoy and Seth W. Troxel 4 Nov. 1993 95 p Sponsored in part by AF Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts DTFA01-93-Z-02012; F19628-90-C-0002)
(AD-A273695; ATC-196; DOT/FAA/RD-93/1) Avail: CASI HC A05

The Federal Aviation Administration has sponsored research and development of algorithms for automatic gust front detection as part of a suite of hazardous weather detection capabilities for airports. These algorithms are intended for use with Doppler radar systems, specifically the Terminal Doppler Weather Radar (TDWR) and the Airport Surveillance Radar enhanced with a Wind Shear Processor (ASR-9 WSP). Although gust fronts are observable with fairly reliable signatures in TDWR data existing gust front detection algorithms have achieved only modest levels of detection performance. For smaller airports not slated to receive a dedicated TDWR, the ASR-9 WSP will provide a less expensive wind shear detection capability. Gust front detection in ASR-9 SP data is an even more difficult problem, given the reduced sensitivity and less reliable Doppler measurements of this radar. A Machine Intelligent Gust Front Algorithm (MIGFA) has been constructed at Lincoln Laboratory. MIGFA is a radical departure from previous design strategies. Incorporating knowledge-based, signal-processing techniques initially developed at Lincoln Laboratory for automatic target recognition, MIGFA uses meteorological knowledge, spatial and temporal context, conditional data fusion, delayed thresholding, and pixel-level fusion of evidence to improve gust front detection performance significantly. In tests comparing MIGFA with an existing state-of-the-art algorithm applied to ASR-9 WSP data, MIGFA has substantially outperformed the older algorithm. DTIC

SOFT GROUND ARRESTING SYSTEM FOR AIRPORTS Final Report
James C. White, Satish K. Agrawal, and Robert E. Cook (Comrise Technologies, Inc.) Dec. 1993 75 p
(DOT/FAA/CT-93/80) Avail: CASI HC A04/MF A01

Aircraft can and do overrun the ends of runways, sometimes with disastrous consequences. Safety overrun areas are designed to provide an additional 1,000 feet of length for stopping overrunning aircraft. At many airports, however, the additional 1,000-foot safety area is not available. At these locations, soft ground arresting systems can be employed to decelerate or stop an overrunning aircraft. A mathematical model representing the interface between the aircraft and the soft ground was developed. This model was used to predict aircraft gear loads, deceleration, and stopping distance within the soft ground system. The validity of the mathematical model was confirmed by eight tests with the use of an instrumented Boeing 727 aircraft. A phenolic foam bed 680 feet long by 48 feet wide and 18 inches deep was used to demonstrate the effectiveness of safely stopping a Boeing 727 aircraft entering the bed at 50 knots and 60 knots: at 50 knots the aircraft came to a complete stop in 420 feet and at 60 knots in 540 feet. The aircraft was successfully extracted from the bed, the foam was successfully repaired, and airport rescue and fire fighting equipment and personnel were able to maneuver without difficulty on the foam. SAFETY STANDARDS FOR AIRCRAFT SHELTER [SIKRINGSAVSTAND FOR FLYBUNKER]
Jens Brandstorp 27 Mar. 1992 69 p In NORWEGIAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(FFI-92/4003; ETN-94-94957) Avail: CASI HC A04

A reexamination of papers concerning Hardened Aircraft Shelter (HAS) explosion tests is presented. Of special interest is the physical background of all the phenomena which occur during or after the internal blast loading on the concrete walls. It is believed that a better physical understanding will benefit the analysis of practical explosion tests. A simulation model which systemizes the physical correlations and thereby predicts the Quantity-Distance (QD) for the debris from aircraft shelters was developed. When the test program of the U.S./Norwegian aircraft shelters in New Mexico (U.S.) are finished during 1992, these results will be compared with those of the simulation model. During the analysis of the earlier tests, a substantial difference in the break up mechanism was proved. This effect causes the size of the model debris to become greater than the full scale debris. A theory concerning this matter is developed. A major difference is also seen between frontside debris and rearside debris QD results. ESA

PROPAGATION OF EXPERIMENTAL UNCERTAINTIES FROM THE TUNNEL TO THE BODY COORDINATE SYSTEM IN 3-D LDV FLOW FIELD STUDIES
Dan H. Neuhart Mar. 1994 46 p
(Contract NAS1-19000; RTOP 505-59-30-04)
(NASA-CR-191607; NAS 1.26:191607) Avail: CASI HC A03/MF A01

An analysis of experimental laser Doppler velocimetry (LDV) data uncertainties that propagate from measurements in the tunnel coordinate system to results in the model system are provided. Calculations of uncertainties as functions of the variables that comprise the final result requires assessment of the contribution each variable makes. Such an analysis enables and necessitates the experimentalists to identify and address the contributing error sources in the experimental measurement system. This provides an opportunity to improve the quality of data derived from experimental systems. This is especially important in experiments where small changes in test conditions are expected to produce small, detectable changes in results. In addition, the need for high-quality experimental data for CFD method validation demands a thorough assessment of experimental uncertainty. Transforming from one Cartesian coordinate system to another by three sequential rotations, equations were developed to transform the variables initially obtained in the original coordinates into variables in the final coordinate system. Based on the transformation equations, propagation equations for errors in the experimentally-derived flow quantities were derived for a model at angle of attack. Experimental uncertainties were then propagated from the tunnel coordinate system into the model system. Author (revised)

EXPERIMENTAL INVESTIGATION OF THE FLOW QUALITY IN THE GLT20 SUBSONIC-TRANSONIC BOUNDARY LAYER WIND TUNNEL
F. Motallebi Apr. 1993 136 p
(PB94-126539; LR-720) Avail: CASI HC A07/MF A02

The design of modern subsonic civil aircrafts requires a detailed knowledge of boundary layer behavior over the aircraft. Wind tunnel experiments are needed to obtain the necessary design information and to provide test data for numerical validations. The primary purpose of the present work was to gather experimental data over the quality of the boundary layer flow developing on the bottom wall of a newly built wind tunnel in order to assess its suitability as an experimental tool for fundamental research on the structure of turbulent boundary layer flows in both subsonic and transonic flow regimes. RECONFIGURABLE AIRCRAFT STICK CONTROL Patent Application
Thomas M. Kelso, inventor (to Navy), John K. Kotch, inventor (to Navy), Damon Boyle, inventor (to Navy), David H. Meiser, inventor (to Navy), and William Flaherty, inventor (to Navy) 29 Sep. 1993 19 p
(AD-D016043; US-Patent-Appl-SN-129729) Avail: CASI HC A03/MF A01

A reconfigurable aircraft stick control for an aircraft simulator that enables pitch and roll to be simulated is presented. It includes a generic base that has mounting means that are adapted to be connected to a stick control of the type having a standard production grip as well as a stick control that uses a yoke. The control sticks include linkages that are easily connected to the mounting means on the base so that control sticks can be exchanged with minimum expenditure of time and effort to thereby simulate the control sticks on aircraft that are being simulated. Torque motors can be connected to the simulator to detect the speed and displacement of the control stick and to provide resistance to movement of the control sticks so as to simulate actual flying conditions. National Aerospace Laboratory (NAL) transonic wind tunnel was constructed in 1960, and in-depth repairs of its superannuated parts was begun in 1985. The newly reconstructed turning vanes are described. The thickness of the turning vanes was 6 mm at first and it was increased to 9 mm in 1968 to prevent cracks caused by fatigue from developing. Despite this increase in thickness, cracks were observed again. With the present reconstruction, the thickness was increased to 12 mm. Tests designed to measure the stresses within the vanes by aerodynamic force and pressure fluctuations of incoming flow were conducted before and after reconstruction. Results from the measurements are presented including a correlation analysis between the stress and the pressure fluctuation. Author (NASDA)

Information for users of the cryogenic wind tunnel is provided. This wind tunnel is a facility with a closed circuit test section. The cross section is 2.4 by 2.4 m. With a drive power of 1 MW, a maximum speed of 115 m/s can be achieved. Dry, gaseous nitrogen is used as the test gas. The test gas can be cooled down to 100 K by injecting liquid nitrogen. By cooling down the test gas, the maximum Reynolds number can be increased by a factor of 5.5 to 9.5 Mio. The independent variation of the test parameters allows the separation of the influence of Mach and Reynolds numbers and dynamic pressure (deformation) on the results. This report provides customers with the information required for the preliminary planning of test programs and for the preliminary layout of models for intended tests. ESA

INSTALLATION OF MODELS IN THE 2 m X 3 m LOW SPEED WIND TUNNEL
K. Hansen Mar. 1991 57 p
(LTR-LA-286; CTN-94-61011) Avail: CASI HC A04/MF A01

Details are provided for installing models in the 2 by 3 meter low speed wind tunnel located in the Building M-2 aeronautical research facilities in the Applied Aerodynamics Laboratory of the Canadian Institute for Aerospace Research. Drawings are included which provide enough information to permit wind tunnel users to prepare models and

instrumentation for attachment in the facility. Only the components which interface between models or instrumentation and permanent wind tunnel hardware are detailed, and usually, only the relevant attachment interface details of the component are presented. A hardware selection guide assists wind tunnel users in selecting appropriate model attachment components. A pictorial review of model installations illustrates the variety of tests performed and demonstrates the adaptability of the wind tunnel facility.

A SIMULATOR INVESTIGATION OF HELICOPTER FLIGHT CONTROL SYSTEM MODE TRANSITIONS
L. D. Reid, P. Rajagopal, and W. O. Graf Jan. 1994 141 p
(Contract W2207-0-AF10) (ISSN 0082-5255)
(UTIAS-348) Copyright Avail: Issuing Activity

The UTIAS Flight Research Simulator was modified to represent a fly-by-wire helicopter with a digital flight control system (FCS) and a side-arm controller. A smooth FCS mode selection algorithm was developed and successfully tested. The pilot/helicopter response to mode transitions was studied for formation flying and precision hover. Both normal and failure-induced transitions were investigated by a group of 9 evaluation pilots. The results were obtained in the form of Cooper/Harper handling qualities ratings (HQR) and station-keeping performance measurements. It was found that for the present mode selection algorithm, the type of mode transition did not significantly influence the experimental results. However, the mode pair (initial mode combined with final mode) was found to influence both HQR's and performance. The mode with the poorest handling qualities was involved in most of the significant effects. In some instances the mode in place before transition influenced the HQR's and performance after transition. Tests were also carried out to study the influence of simulator configuration on the experimental results. In addition to the standard configuration, one with no motion and one using a stereoscopic visual display system were employed. In general no significant effects were found except in one instance when there was a significant difference between the no-motion and stereoscopic configurations. Author

SIMULATING HIGH-FREQUENCY WIND FOR LONG DURATIONS
Andrew McFarlane (Cherry Creek High School, Englewood, CO.), Paul Veers, and Larry Schluter 1993 11 p Presented at the 13th Energy-Sources Technology Conference and Exhibition (ETCE) on Wind Energy, New Orleans, LA, 23-26 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-002739; SAND-93-1584C; CONF-940113-4) Avail: CASI HC A03/MF A01 (US Sales Only)

A wind simulator that can provide high-frequency synthetic wind data indefinitely was developed to numerically test various aspects of wind turbine control systems. The wind simulator builds synthetic wind data in two basic steps. First, using an auto-regressive method, the simulator creates low-frequency wind speeds at a small number of time steps for each one-hour interval. This low-frequency part of the wind has a Weibull distribution and an exponential auto correlation. Second, it creates high-frequency data and superimposes it on top of the low-frequency wind speed data. The high-frequency part has zero mean, Gaussian distribution and frequency content selected from a library of turbulence pads. The low- and high-frequency parts are summed to produce the final result. This process repeats itself for as many one-hour intervals as the user desires and lends itself to the eventual addition of diurnal and seasonal effects.

Space activities have existed for 34 years around the world. Demanding technology operating in extreme conditions has been developed for space projects, instruments, satellites and shuttles. The nature of space technology is basic development and it also serves well the purposes of conventional, industrial and commercial applications. ESA's industrial return makes it possible for the industry and research organizations to participate in space projects. In that way, Finland has a possibility to widen its technological know-how base, get technology knowledge for developing new commercial products, and get a base for controlling quality. Many of the space instrument and Earth observation projects (for example, GOMOS ozone analyzer) are also socially important. ESA

Papers and abstracts included represent both formal presentations and experimental demonstrations at the Workshop on Selected Topics in Robotics for Space Exploration which took place at NASA Langley Research Center, 17-18 March 1993. The workshop was cosponsored by the Guidance, Navigation, and Control Technical Committee of the NASA Langley Research Center and the Center for Intelligent Robotic Systems for Space Exploration (CIRSSE) at RPI, Troy, NY. Participation was from industry, government, and other universities with close ties to either Langley Research Center or to CIRSSE. The presentations were very broad in scope with attention given to space assembly, space exploration, flexible structure control, and telerobotics. For individual titles, see N94-26279 through N94-26292.

A GLOBAL APPROACH TO KINEMATIC PATH PLANNING TO ROBOTS WITH HOLONOMIC AND NONHOLONOMIC CONSTRAINTS

Adam Divelbiss, Sanjeev Seereeram, and John T. Wen *In* NASA. Langley Research Center, Selected Topics in Robotics for Space Exploration Dec. 1993 p 3-25 (For primary document see N94-26278 07-12)

Avail: CASI HC A03/MF A03

Robots in applications may be subject to holonomic or nonholonomic constraints. Examples of holonomic constraints include a manipulator constrained through the contact with the environment, e.g., inserting a part, turning a crank, etc., and multiple manipulators constrained through a common payload. Examples of nonholonomic constraints include no-slip constraints on mobile robot wheels, local normal rotation constraints for soft finger and rolling contacts in grasping, and conservation of angular momentum of in-orbit space robots. The above examples all involve equality constraints; in applications, there are usually additional inequality constraints such as robot joint limits, self collision and environment collision avoidance constraints, steering angle constraints in mobile robots, etc. The problem of finding a kinematically feasible path that satisfies a given set of holonomic and nonholonomic constraints, of both equality and inequality types is addressed. The path planning problem is first posed as a finite time nonlinear control problem. This problem is subsequently transformed to a static root finding problem in an augmented space which can then be iteratively solved. The algorithm has shown promising results in planning feasible paths for redundant arms satisfying Cartesian path following and goal endpoint specifications, and mobile vehicles with multiple trailers. In contrast to local approaches, this algorithm is less prone to problems such as singularities and local minima. Author (revised)

APPLICATION OF THE CIRSSE COOPERATING ROBOT PATH PLANNER TO THE NASA LANGLEY TRUSS ASSEMBLY PROBLEM **c63**

Jonathan M. Weaver and Stephen J. Derby *In* NASA. Langley Research Center, Selected Topics in Robotics for Space Exploration Dec. 1993 p 28-35 Sponsored by NASA, Washington (For primary document see N94-26278 07-12)

(Grant NAGw-1333)

Avail: CASI HC A02/MF A03

A method for autonomously planning collision free paths for two cooperating robots in a static environment was developed at the Center for Intelligent Robotic Systems for Space Exploration (CIRSSE). The method utilizes a divide-and-conquer type of heuristic and involves non-exhaustive mapping of configuration space. While there is no guarantee of finding a solution, the planner was successfully applied to a variety of problems including two cooperating 9 degrees of freedom (dof) robots. Although developed primarily for cooperating robots the method is also applicable to single robot path planning problems. A single 6 dof version of the planner was implemented for the truss assembly east, at NASA Langley's Automated Structural Assembly Lab (ASAL). The results indicate that the planner could be very useful in addressing the ASAL path planning problem and that further work along these lines is warranted. Author (revised)

INERTIAL-SPACE DISTURBANCE REJECTION FOR SPACE-BASED MANIPULATORS **c37**

Kevin Holt and Alan A. Desrochers *In* NASA. Langley Research Center, Selected Topics in Robotics for Space Exploration Dec. 1993 p 37-43 (For primary document see N94-26278 07-12)

Avail: CASI HC A02/MF A03

The implementation of a disturbance rejection controller for a 6-DOF PUMA manipulator mounted on a 3-DOF platform was described. A control algorithm is designed to track the desired position and attitude of the end-effector in inertial space, subject to unknown disturbances in the platform axes. Experimental results are presented for step, sinusoidal, and random disturbances in the platform rotational axis and in the neighborhood of kinematic singularities. Robotic manipulators were proposed as a means of reducing the amount of extra vehicular activity time required for space station assembly and maintenance. The proposed scenario involves a robotic manipulator attached to some mobile platform, such as a spacecraft, satellite, or the space station itself. Disturbances in the platform position and attitude may prevent the manipulator from successfully completing the task. The possibility of using the manipulator to compensate for platform disturbances was explored. The problem of controlling a robotic manipulator on a mobile platform has received considerable attention in the past few years. Joshi and Desrochers designed a nonlinear feedback control law to carry out tasks (with respect to the robot base frame) in the presence of roll, pitch and yaw disturbances in the platform axes. Dubowsky, Vance, and Torres proposed a time-optimal planning algorithm for a robotic manipulator mounted on a spacecraft, subject to saturation limits in the attitude control reaction jets. Papadopoulos and Dubowsky developed a general framework for analyzing the control of free-floating space manipulator systems. Most recently, Torres and Dubowsky have presented a technique called the enhanced disturbance map to find manipulator trajectories that reduce the effect of disturbances in the spacecraft position and attitude. One common assumption in the literature is that the disturbance signal is exactly known. If this is the case, then the end-effector location can be calculated without relying on direct end-point sensing. However, this assumption is invalid if there is a significant delay in the platform position and attitude measurements, or if the kinematics of the platform are not well known, or if the platform is a non-rigid structure. In the more likely case that only the nominal platform location and upper bound on the disturbance signal are known, direct end-point sensing is needed to measure the end-effector location. DIRECT MODEL REFERENCE ADAPTIVE CONTROL OF ROBOTIC ARMS **c37**

Howard Kaufman, David C. Swift, Steven T. Cummings, and Jeffrey R. Shankey *In* NASA. Langley Research Center, Selected Topics in Robotics for Space Exploration Dec. 1993 p 45-71 (For primary document see N94-26278 07-12)

Avail: CASI HC A03/MF A03

The results of controlling A PUMA 560 Robotic Manipulator and the NASA shuttle Remote Manipulator System (RMS) using a Command Generator Tracker (CGT) based Model Reference Adaptive Controller (DMRAC) are presented. Initially, the DMRAC algorithm was run in simulation using a detailed dynamic model of the PUMA 560. The algorithm was tuned on the simulation and then used to control the manipulator using minimum jerk trajectories as the desired reference inputs. The ability to track a trajectory in the presence of load changes was also investigated in the simulation. Satisfactory performance was achieved in both simulation and on the actual robot. The obtained responses showed that the algorithm was robust in the presence of sudden load changes. Because these results indicate that the DMRAC algorithm can indeed be successfully applied to the control of robotic manipulators, additional testing was performed to validate the applicability of DMRAC to simulated dynamics of the shuttle RMS. PERFORMANCE MEASURES FROM THE EXPLORER PLATFORM BERTHING EXPERIMENT **c18**

Stephen Leake *In* NASA. Langley Research Center, Selected Topics in Robotics for Space Exploration Dec. 1993 p 73-94 (For primary document see N94-26278 07-12)

Avail: CASI HC A03/MF A03

The Explorer Platform is a Modular Mission Spacecraft: it has several subunits that are designed to be replaced on orbit. The Goddard Space Flight Center Robotics Lab undertook an experiment to evaluate various robotic approaches to replacing one of the units; a large (approximately 1 meter by 1 meter by 0.5 meter) power box. The hardware consists of a Robotics Research Corporation K-1607 (RRC) manipulator mounted on a large gantry robot, a Kraft handcontroller for teleoperation of RRC, a Lightweight Servicing Tool (LST) mounted on the RRC, and an Explorer Platform mockup (EP) with a removable box (MMS) that has fixtures that mate with the LST. Sensors include a wrist wrench sensor on the RRC and Capaciflectors mounted on the LST and the MMS. There are also several cameras, but no machine vision is used. The control system for the RRC is entirely written by Goddard; it consists of Ada code on three Multibus I 386/387 CPU boards doing the real-time robot control, and C on a 386 PC processing Capaciflector data. The gantry is not moved during this experiment. The task is the exchange of the MMS; it is removed and replaced. This involves four basic steps: mating the LST to the MMS, demating the MMS from the EP, mating the MMS to the EP, and demating the LST form the MMS. Each of the mating steps must be preceeded by an alignment to bring the mechanical fixtures within their capture range. Two basic approaches to alignment are explored: teleoperation with the operator viewing thru cameras, and Capaciflector based autonomy. To evaluate the two alignment approaches, several runs were run with each approach and the final pose was recorded. Comparing this to the ideal alignment pose gives accuracy and repeatability data. In addition the wrenches exerted during the mating tasks were recorded; this gives information on how the alignment step affects the mating step. There are also two approaches to mating; teleoperation, and impedance based autonomy. The wrench data taken during mating using these two approaches is used to evaluate them. Section 2 describes the alignment results, section 3 describes the mating results, and finally Section 4 gives some conclusions. Author (revised)

Avail: CASI HC A03/MF A03

A large-angle, flexible, multi-body, dynamic modeling capability was developed to help validate analytical simulations of the dynamic motion and control forces which occur while berthing of Space Station Freedom to the Shuttle Orbiter during early assembly flights. The dynamics and control of the station, the attached Shuttle Remote Manipulator System, and the Orbiter during a berthing maneuver are described. Emphasis is placed on the modeling of the Shuttle Remote Manipulator System in the multi-body simulation. The influence of the elastic behavior of the station and of the Remote Manipulator System on the attitude control of the station/Orbiter system during the maneuver is investigated. Author (revised)

The use of simulation is described and it is contrasted to analytical solution techniques for evaluation of analytical reliability models. The role importance sampling plays in simulation of models of this type was also discussed. The simulator tool used for our analysis is described. Finally, the use of the simulator tool was demonstrated by applying it to evaluate the reliability of a fault tolerant hypercube multiprocessor intended for spacecraft designed for long duration missions. The reliability analysis was used to highlight the advantages and disadvantages offered by simulation over analytical solution of Markovian and non-Markovian reliability models. Author (revised)

THE ROBOTIC ALL-TERRAIN LUNAR EXPLORATION ROVER (RATLER): INCREASED MOBILITY THROUGH SIMPLICITY **c91**

J. Bryan Pletta *In* NASA. Langley Research Center, Selected Topics in Robotics for Space Exploration Dec. 1993 p 247-267 (For primary document see N94-26278 07-12)

Avail: CASI HC A03/MF A03

A new concept mobility chassis for a robotic rover is described which is inherently simple with few moving parts or complex linkages. The RATLER design utilizes a four-wheel drive, skid steered propulsion system in conjunction with passive articulation of the dual body vehicle. This uniquely simple method of chassis articulation allows all four wheels to remain in contact with the ground even while climbing obstacles as large as 1.3 wheel diameters. A prototype mobility platform was built which is approximately 1 m(sup 2) with 0.5 m diameter wheels and all-wheel electric drive. The theoretical mobility limitations are discussed and compared with the results of field trials of the prototype platform. The theoretical model contrasted with measured performance is then used to predict the expected mobility of the RATLER design on the Lunar surface. Author (revised)

A MULTITASKING BEHAVIORAL CONTROL SYSTEM FOR THE ROBOTIC ALL-TERRAIN LUNAR EXPLORATION ROVER (RATLER) **c37**

Paul Klarer *In* NASA. Langley Research Center, Selected Topics in Robotics for Space Exploration Dec. 1993 p 269-278 (For primary document see N94-26278 07-12)

Avail: CASI HC A02/MF A03

An approach for a robotic control system which implements so called 'behavioral' control within a realtime multitasking architecture is proposed. The proposed system would attempt to ameliorate some of the problems noted by some researchers when implementing subsumptive or behavioral control systems, particularly with regard to multiple processor systems and realtime operations. The architecture is designed to allow synchronous operations between various behavior modules by taking advantage of a realtime multitasking system's intertask communications channels, and by implementing each behavior module and each interconnection node as a stand-alone task. The potential advantages of this approach over those previously described in the field are discussed. An implementation of the architecture is planned for a prototype Robotic All Terrain Lunar Exploration Rover (RATLER) currently under development and is briefly described. Author (revised)

ACCESS TO SPACE STUDY Summary Report

Jan. 1994 78 p

(NASA-TM-109693; NAS 1.15:109693) Avail: CASI HC A05/MF A01

This report summarizes the results of a comprehensive NASA in-house study to identify and assess alternate approaches to access to space through the year 2030, and to select and recommend a preferred cause of action. The goals of the study were to identify the best vehicles and transportation architectures to make major reductions in the cost of space transportation (at least 50%), while at the same time increasing safety for flight crews by at least an order of magnitude. In addition, vehicle reliability was to exceed 0.98 percent, and, as important, the robustness, pad time, turnaround time, and other aspects of operability were to be vastly improved. This study examined three major optional architectures: (1) retain and upgrade the Space Shuttle and expendable launch vehicles; (2) develop new expendable vehicles using conventional technologies and transition from current vehicles beginning in 2005; and (3) develop new reusable vehicles using advanced technology, and transition from current vehicles beginning in 2008. The launch-needs, mission model utilized for for the study was based upon today's projection of civil, defense, and commercial mission payload requirements. Derived from text

VISION 21: INTERDISCIPLINARY SCIENCE AND ENGINEERING IN THE ERA OF CYBERSPACE

Dec. 1993 274 p Symposium held in Westlake, OH, 30-31 Mar. 1993; cosponsored by Ohio Aerospace Inst.

(Contract NAS3-25266; RTOP 506-41-11)

(NASA-CP-10129; E-8238; NAS 1.55:10129) Avail: CASI HC A12/MF A03

The symposium Vision-21: Interdisciplinary Science and Engineering in the Era of Cyberspace was held at the NASA Lewis Research Center on March 30-31, 1993. The purpose of the symposium was to simulate interdisciplinary thinking in the sciences and technologies which will be required for exploration and development of space over the next thousand years. The keynote speakers were Hans Moravec, Vernor Vinge, Carol Stoker, and Myron Krueger. The proceedings consist of transcripts of the invited talks and the panel discussion by the invited speakers, summaries of workshop sessions, and contributed papers by the attendees. For individual titles, see N94-27359 through N94-27376.

THE COMING TECHNOLOGICAL SINGULARITY: HOW TO SURVIVE IN THE POST-HUMAN ERA

Vernor Vinge *In* NASA. Lewis Research Center, Vision 21: Interdisciplinary Science and Engineering in the Era of Cyberspace Dec. 1993 p 11-22 (For primary document see N94-27358 07-12)

Avail: CASI HC A03/MF A03

The acceleration of technological progress has been the central feature of this century. I argue in this paper that we are on the edge of change comparable to the rise of human life on Earth. The precise cause of this change is the imminent creation by technology of entities with greater than human intelligence. There are several means by which science may achieve this breakthrough (and this is another reason for having confidence that the event will occur): (1) the development of computers that are 'awake' and superhumanly intelligent (to date, most controversy in the area of AI relates to whether we can create human equivalence in a machine. But if the answer is 'yes, we can', then there is little doubt that beings more intelligent can be constructed shortly thereafter); (2) large computer networks (and their associated users) may 'wake up' as a superhumanly intelligent entity; (3) computer/human interfaces may become so intimate that users may reasonably be considered superhumanly intelligent; and (4) biological science may find ways to improve upon the natural human intellect. The first three possibilities depend in large part on improvements in computer hardware. Progress in computer hardware has followed an amazingly steady curve in the last few decades. Based largely on this trend, I believe that the creation of greater than human intelligence will occur during the next thirty years. Derived from text

TELEPRESENCE IN THE HUMAN EXPLORATION OF MARS: FIELD STUDIES IN ANALOG ENVIRONMENTS **c91**

Carol R. Stoker *In* NASA. Lewis Research Center, Vision 21: Interdisciplinary Science and Engineering in the Era of Cyberspace Dec. 1993 p 23-34 (For primary document see N94-27358 07-12)

Avail: CASI HC A03/MF A03

This paper describes the role of telepresence in performing exploration of Mars. As part of an effort to develop telepresence to support Mars exploration, NASA is developing telepresence technology and using it to perform exploration in space analog environments. This paper describes experiments to demonstrate telepresence control of an underwater remotely operated vehicle (TROV) to perform scientific field work in isolated and hostile environments. Toward this end, we have developed a telepresence control system and interfaced it to an underwater remotely operated vehicle. This vehicle was used during 1992 to study aquatic ecosystems in Antarctica including a study of the physical and biological environment of permanently ice-covered lake. We also performed a preliminary analysis of the potential for using the TROV to study the benthic ecology under the sea ice in McMurdo sound. These expeditions are opening up new areas of research by using telepresence control of remote vehicles to explore isolated and extreme environments on Earth while also providing an impetus to develop technology which will play a major role in the human exploration of Mars. Antarctic field operations, in particular, provide an excellent analog experience for telepresence operation in space. Author

Our artifacts are getting smarter, and a loose parallel with the evolution of animal intelligence suggests one future course for them. Computerless industrial machinery exhibits the behavioral flexibility of single-celled organisms. Today's best computer-controlled robots are like the simpler invertebrates. A thousand-fold increase in computer power in the next decade should make possible machines with reptile-like sensory and motor competence. Properly configured, such robots could do in the physical world what personal computers now do in the world of data - act on our behalf as literal-minded slaves. Growing computer power over the next half-century will allow this reptile stage to be surpassed, in stages producing robots that learn like mammals, model their world like primates, and eventually reason like humans. Depending on your point of view, humanity will then have produced a worthy successor, or transcended some of its inherited limitations and so transformed itself into something quite new. Author

The 'computational test-cell' will enable the incorporation of new methodologies, such as concurrent engineering and probabilistic methods, into the propulsion design process. This will provide the capability to conduct credible, interdisciplinary analyses of new propulsion concepts and designs. Probabilistic methods can be used as the basis for reliability-based design. Recently methods have been devised that provide the capability of simulating the performance of propulsion systems at several levels of resolution. These methods make it possible to quantify uncertainty and to establish confidence bounds for the calculated values. The introduction of reliability-based design methodology along with probabilistic analyses will provide a tool to reduce the design space for new systems and to reduce our dependence on hardware testing for proof-of-concept and system integration demonstrations. The resulting simulations will reduce the need for testing and identify potential operational problems early in the design process. This capability will make it possible to compute the expected performance, stability, reliability, and life of propulsion components, subsystems, and systems at design and off-design conditions, to bring life cycle cost trade-offs early into the design process and to determine optimum designs to satisfy specified mission requirements. PARALLEL ALGORITHM FOR DOMINANT POINTS CORRESPONDENCES IN ROBOT BINOCULAR STEREO VISION c61
A. Al-Tammami and B. Singh *In* NASA. Lewis Research Center, Vision 21: Interdisciplinary Science and Engineering in the Era of Cyberspace Dec. 1993 p 71-81 (For primary document see N94-27358 07-12)
Avail: CASI HC A03/MF A03

This paper presents an algorithm to find the correspondences of points representing dominant feature in robot stereo vision. The algorithm consists of two main steps: dominant point extraction and dominant point matching. In the feature extraction phase, the algorithm utilizes the widely used Moravec Interest Operator and two other operators: the Prewitt Operator and a new operator called Gradient Angle Variance Operator. The Interest Operator in the Moravec algorithm was used to exclude featureless areas and simple edges which are oriented in the vertical, horizontal, and two diagonals. It was incorrectly detecting points on edges which are not on the four main directions (vertical, horizontal, and two diagonals). The new algorithm uses the Prewitt operator to exclude featureless areas, so that the Interest Operator is applied only on the edges to exclude simple edges and to leave interesting points. This modification speeds-up the extraction process by approximately 5 times. The Gradient Angle Variance (GAV), an operator which calculates the variance of the gradient angle in a window around the point under concern, is then applied on the interesting points to exclude the redundant ones and leave the actual dominant ones. The matching phase is performed after the extraction of the dominant points in both stereo images. The matching starts with dominant points in the left image and does a local search, looking for corresponding dominant points in the right image. The search is geometrically constrained the epipolar line of the parallel-axes stereo geometry and the maximum disparity of the application environment. If one dominant point in the right image lies in the search areas, then it is the corresponding point of the reference dominant point in the left image. A parameter provided by the GAV is thresholded and used as a rough similarity measure to select the corresponding dominant point if there is more than one point the search area. The correlation is used as a final decision tool when there is still more than one point in the search area. If there is no dominant point in the search area of if the points in the search area are below a correlation threshold, then the dominant point in the reference image is occluded and can not be corresponded. The algorithm has been modeled, implemented and shown to be fast, robust and parallel. The parallelism is created from three main features: locality of the operators; a memory optimization scheme; and the ability to fully parallelize the extraction phase which is the most computational intensive task in the algorithm. The last feature is achieved by performing the extraction phase on the two images simultaneously. Author

SCULPTING IN CYBERSPACE: PARALLEL PROCESSING THE DEVELOPMENT OF NEW SOFTWARE c62
Rob Fisher *In* NASA. Lewis Research Center, Vision 21: Interdisciplinary Science and Engineering in the Era of Cyberspace Dec. 1993 p 83-99 (For primary document see N94-27358 07-12)
Avail: CASI HC A03/MF A03

Stimulating creativity in problem solving, particularly where software development is involved, is applicable to many disciplines. Metaphorical thinking keeps the problem in focus but in a different light, jarring people out of their mental ruts and sparking fresh insights. It forces the mind to stretch to find patterns between dissimilar concepts, in the hope of discovering unusual ideas in odd associations (Technology Review January 1993, p. 37). With a background in Engineering and Visual Design from MIT, I have for the past 30 years pursued a career as a sculptor of interdisciplinary monumental artworks that bridge the fields of science, engineering and art. Since 1979, I have pioneered the application of computer simulation to solve the complex problems associated with these projects. A recent project for the roof of the Carnegie Science Center in Pittsburgh made particular use of the metaphoric creativity technique described above. The problem-solving process led to the creation of hybrid software combining scientific, architectural and engineering visualization techniques. David Steich, a Doctoral Candidate in Electrical Engineering at Penn State, was commissioned to develop special software that enabled me to create innovative free-form sculpture. This paper explores the process of inventing the software through a detailed analysis of the interaction between an artist and a computer programmer. Author

This paper details a plan to explore the galaxy. Areas of interest to an era of cyberspace include the Tech-Index information system for the expedition and the role cyberspace has in increasing expedition productivity and increasing the capabilities of cyberspace by expanding the goals and data set. The paper offers lists of projects for the cybermarket pool. The expedition is described also as a developers tool for cyberspace to acknowledge the scope of the human mind far surpasses present engineering yet guides our direction of energies and materials. Maintaining the biological capability to reproduce the Terran biosphere via Evolution park conservation areas is discussed. The ecological repair of Spaceship Earth and the build up of an interstellar industrial base from simple recyling and educational programs is meshed with a proposed 'reverse engineering cyberspace' plan. A set of constructive contests are proposed with 3 new currencies offered as prizes. The Planet, The Solar System, The Galaxy are 3 areas of focus. Each of these areas are considered in a cyberspectrum of (1) Sentience; (2) Biological diversity; and (3) Energy/Matter resources. Author

SPACE STATION TECHNOLOGY TESTBED: 2010 DEEP SPACE TRANSPORT c18

Alan C. Holt *In* NASA. Lewis Research Center, Vision 21: Interdisciplinary Science and Engineering in the Era of Cyberspace Dec. 1993 p 127-151 (For primary document see N94-27358 07-12)
Avail: CASI HC A03/MF A03

A space station in a crew-tended or permanently crewed configuration will provide major R&D opportunities for innovative, technology and materials development and advanced space systems testing. A space station should be designed with the basic infrastructure elements required to grow into a major systems technology testbed. This space-based technology testbed can and should be used to support the development of technologies required to expand our utilization of near-Earth space, the Moon and the Earth-to-Jupiter region of the Solar System. Space station support of advanced technology and materials development will result in new techniques for high priority scientific research and the knowledge and R&D base needed for the development of major, new commercial product thrusts. To illustrate the technology testbed potential of a space station and to point the way to a bold, innovative approach to advanced space systems' development, a hypothetical deep space transport development and test plan is described. Key deep space transport R&D activities are described would lead to the readiness certification of an advanced, reusable interplanetary transport capable of supporting eight crewmembers or more. With the support of a focused and highly motivated, multi-agency ground R&D program, a deep space transport of this type could be assembled and tested by 2010. Key R&D activities on a space station would include: (1) experimental research investigating the microgravity assisted, restructuring of micro-engineered, materials (to develop and verify the in-space and in-situ 'tuning' of materials for use in debris and radiation shielding and other protective systems), (2) exposure of microengineered materials to the space environment for passive and operational performance tests (to develop in-situ maintenance and repair techniques and to support the development, enhancement, and implementation of protective systems, data and bio-processing systems, and virtual reality and telepresence/kinetic processes), (3) subsystem tests of advanced nuclear power, nuclear propulsion and communication systems (using boom extensions, remote station-keeping platforms and mobile EVA crew and robots), and (4) logistics support (crew and equipment) and command and control of deep space transport assembly, maintenance, and refueling (using a station-keeping platform). AN ARTIFICIAL REALITY ENVIRONMENT FOR REMOTE FACTORY CONTROL AND MONITORING c31

Charles Paul Kosta and Patrick D. Krolak *In* NASA. Lewis Research Center, Vision 21: Interdisciplinary Science and Engineering in the Era of Cyberspace Dec. 1993 p 153-162 (For primary document see N94-27358 07-12)
Avail: CASI HC A02/MF A03

Work has begun on the merger of two well known systems, VEOS (HITLab) and CLIPS (NASA). In the recent past, the University of Massachusetts Lowell developed a parallel version of NASA CLIPS, called P-CLIPS. This modification allows users to create smaller expert systems which are able to communicate with each other to jointly solve problems. With the merger of a VEOS message system, PCLIPS-V can now act as a group of entities working within VEOS. To display the 3D virtual world we have been using a graphics package called HOOPS, from Ithaca Software. The artificial reality environment we have set up contains actors and objects as found in our Lincoln Logs Factory of the Future project. The environment allows us to view and control the objects within the virtual world. All communication between the separate CLIPS expert systems is done through VEOS. A graphical renderer generates camera views on X-Windows devices; Head Mounted Devices are not required. This allows more people to make use of this technology. We are experimenting with different types of virtual vehicles to give the user a sense that he or she is actually moving around inside the factory looking ahead through windows and virtual monitors. THE FERMI PARADOX: AN APPROACH BASED ON PERCOLATION THEORY c55

Geoffrey A. Landis *In* NASA. Lewis Research Center, Vision 21: Interdisciplinary Science and Engineering in the Era of Cyberspace Dec. 1993 p 163-167 (For primary document see N94-27358 07-12)
Avail: CASI HC A01/MF A03

If even a very small fraction of the hundred billion stars in the galaxy are home to technological civilizations which colonize over interstellar distances, the entire galaxy could be completely colonized in a few million years. The absence of such extraterrestrial civilizations visiting Earth is the Fermi paradox. A model for interstellar colonization is proposed using the assumption that there is a maximum distance over which direct interstellar colonization is feasible. Due to the time lag involved in interstellar communications, it is assumed that an interstellar colony will rapidly develop a culture independent of the civilization that originally settled it. Any given colony will have a probability P of developing a colonizing civilization, and a probability (1-P) that it will develop a non-colonizing civilization. These assumptions lead to the colonization of the galaxy occuring as a percolation problem. In a percolation problem, there will be a critical value of percolation probability, P(sub c). For P less than P(sub c), colonization will always terminate after a finite number of colonies. Growth will occur in 'clusters', with the outside of each cluster consisting of non-colonizing civilizations. For P greater than P(sub c), small uncolonized voids will exist, bounded by non-colonizing civilizations. For P approximately = to P(sub c), arbitrarily large filled regions exist, and also arbitrarily large empty regions. Author

A DIRECT CURRENT RECTIFICATION SCHEME FOR MICROWAVE SPACE POWER CONVERSION USING TRAVELING WAVE ELECTRON ACCELERATION c20

Robert M. Manning *In its* Vision 21: Interdisciplinary Science and Engineering in the Era of Cyberspace Dec. 1993 p 169-178 (For

primary document see N94-27358 07-12)
Avail: CASI HC A02/MF A03

The formation of the Vision-21 conference held three years ago allowed the present author to reflect and speculate on the problem of converting electromagnetic energy to a direct current by essentially reversing the process used in traveling wave tubes that converts energy in the form of a direct current to electromagnetic energy. The idea was to use the electric field of the electromagnetic wave to produce electrons through the field emission process and accelerate these electrons by the same field to produce an electric current across a large potential difference. The acceleration process was that of cyclotron auto-resonance. Since that time, this rather speculative ideas has been developed into a method that shows great promise and for which a patent is pending and a prototype design will be demonstrated in a potential laser power beaming application. From the point of view of the author, a forum such as Vision-21 is becoming an essential component in the rather conservative climate in which our initiatives for space exploration are presently formed. Exchanges such as Vision-21 not only allows us to deviate from the 'by-the-book' approach and rediscover the ability and power in imagination, but provides for the discussion of ideas hitherto considered 'crazy' so that they may be given the change to transcend from the level of eccentricity to applicability. EMERGING COMPUTER TECHNOLOGIES AND THE NEWS MEDIA OF THE FUTURE **c60**
Debra A. Vrabel *In* NASA. Lewis Research Center, Vision 21: Interdisciplinary Science and Engineering in the Era of Cyberspace Dec. 1993 p 181-183 (For primary document see N94-27358 07-12)
Avail: CASI HC A01/MF A03

The media environment of the future may be dramatically different from what exists today. As new computing and communications technologies evolve and synthesize to form a global, integrated communications system of networks, public domain hardware and software, and consumer products, it will be possible for citizens to fulfill most information needs at any time and from any place, to obtain desired information easily and quickly, to obtain information in a variety of forms, and to experience and interact with information in a variety of ways. This system will transform almost every institution, every profession, and every aspect of human life--including the creation, packaging, and distribution of news and information by media organizations. This paper presents one vision of a 21st century global information system and how it might be used by citizens. It surveys some of the technologies now on the market that are paving the way for new media environment. Author

INERTIAL ELECTROSTATIC CONFINEMENT AS A POWER SOURCE FOR ELECTRIC PROPULSION **c20**
George H. Miley (Illinois Univ., Urbana.), R. Burton (Illinois Univ., Urbana.), J. Javedani (Illinois Univ., Urbana.), Y. Yamamoto (Illinois Univ., Urbana.), A. Satsangi (Illinois Univ., Urbana.), Y. Gu (Illinois Univ., Urbana.), P. Heck (Illinois Univ., Urbana.), R. Nebel (Los Alamos National Lab., NM.), N. Schulze (Illinois Univ., Urbana.), and J. Christensen (Illinois Univ., Urbana.) et al *In* NASA. Lewis Research Center, Vision 21: Interdisciplinary Science and Engineering in the Era of Cyberspace Dec. 1993 p 185-229 (For primary document see N94-27358 07-12)
Avail: CASI HC A03/MF A03

The potential use of an Inertial Electrostatic Confinement (IEC) power source for space propulsion has previously been suggested by the authors and others. In the past, these discussions have generally followed the charged-particle electric-discharge engine (QED) concept proposed by Bussard, in which the IEC is used to generate an electron beam which vaporizes liquid hydrogen for use as a propellant. However, in the present study, we consider an alternate approach, using the IEC to drive a conventional electric thruster unit. This has the advantage of building on the rapidly developing technology for such thrusters, which operate at higher specific impulse. Key issues related to this approach include the continued successful development of the physics and engineering of the IEC unit, as well as the development of efficient step-down dc voltage transformers. The IEC operates by radial injection of energetic ions into a spherical vessel. A very high ion density is created in a small core region at the center of the vessel, resulting in extremely high fusion power density in the core. Present experiments at the U. of Illinois in small IEC devices (less than 60-cm. dia.) have demonstrated much of the basic physics underlying this concept, e.g. producing approximately 10(exp 6) D-D neutrons/sec steady-state with deuterium gas flow injection. The ultimate goal is to increase the power densities by several orders of magnitude and to convert to D-He-3 injection. If successful, such an experiment would represent a milestone proof-of-principle device for eventual space power use. Further discussion of IEC physics and status will be presented with a description of the overall propulsion system and estimated performance. Author

A WIDELY ADAPTABLE HABITAT CONSTRUCTION SYSTEM UTILIZING SPACE RESOURCES **c54**
Harry B. Wykes *In* NASA. Lewis Research Center, Vision 21: Interdisciplinary Science and Engineering in the Era of Cyberspace Dec. 1993 p 231-240 (For primary document see N94-27358 07-12)
Avail: CASI HC A02/MF A03

This study suggests that the cost of providing accommodations for various manned activities in space may be reduced by the extensive use of resources that are commonly found throughout the solar system. Several concepts are proposed for converting these resources into simple products with many uses. Concrete is already being considered as a possible moonbase material. Manufacturing equipment should be as small and simple as possible, which leads to the idea of molding it into miniature modules that can be produced and assembled in large numbers to create any conceivable shape. Automated equipment could build up complex structures by laying down layer after layer in a process resembling stereolithography. These tiny concrete blocks handle compression loads and provide a barrier to harmful radiation. They are joined by a web of tension members that could be made of wire or fiber-reinforced plastic. The finished structure becomes air-tight with the addition of a flexible liner. Wire can be made from the iron modules found in lunar soil. In addition to its structural role, a relatively simple apparatus can bend and weld it into countless products like chairs and shelving that would otherwise need to be supplied from Earth. Wire woven into a loose blanket could be an effective micrometeoroid shield, tiny wire compression beams could be assembled into larger beams which in turn form larger beams to create very large space-frame structures. A technology developed with lunar materials could be applied to the moons of Mars or the asteroids. To illustrate its usefulness several designs for free-flying habitats are presented. They begin with a minimal self-contained living unit called the Cubicle. It may be multiplied into clusters called Condos. These are shown in a rotating tether configuration that provides a substitute for gravity. The miniature block proposal is compared with an alternate design based on larger triangular components and a tetrahedral geometry. The overall concept may be expanded to envision city-sized self-sufficient environments where humans could confortably live their entire lives. One such proposal is the Hive. It is configured around a unique sunlight collection system that could provide all its energy needs and that could be scaled up to compensate for the reduced solar intensity at greater distances from the sun. Its outer perimeter consists of a cylindrical section mated to two conical end walls that taper inwards toward a small aperture at the center of rotation. Light collected by two huge mirrors of unusual design enters the aperture and is redirected to the inside of the cylinder. The conical end walls are shielded from direct sunlight and are designed to radiate heat into space. They are lined with air ducts that passively recirculate the atmosphere while extracting moisture by condensation. Although there is no immediate demand for spacecraft on this scale, their consideration can influence even the earliest stages of the development process. Author

Exploration and colonization of the universe awaits, but Earth-adapted biological humans are ill-equipped to respond to the challenge. Machines have gone farther and seen more, limited though they presently are by insect-like behavior inflexibility. As they become smarter over the coming decades, space will be theirs. Organizations of robots of ever increasing intelligence and sensory and motor ability will expand and transform what they occupy, working with matter, space and time. As they grow, a smaller and smaller fraction of their territory will be undeveloped frontier. Competitive success will depend more and more on using already available matter and space in ever more refined and useful forms. The process, analogous to the miniaturization that makes today's computers a trillion times more powerful than the mechanical calculators of the past, will gradually transform all activity from grossly physical homesteading of raw nature, to minimum-energy quantum transactions of computation. The final frontier will be urbanized, ultimately into an arena where every bit of activity is a meaningful computation: the inhabited portion of the universe will be transformed into a cyberspace. Because it will use resources more efficiently, a mature cyberspace of the distant future will be effectively much bigger than the present physical universe. While only an infinitesimal fraction of existing matter and space is doing interesting work, in a well developed cyberspace every bit will be part of a relevant computation or storing a useful datum. Over time, more compact and faster ways of using space and matter will be invented, and used to restructure the cyberspace, effectively increasing the amount of computational spacetime per unit of physical spacetime. Computational speed-ups will affect the subjective experience of entities in the cyberspace in a paradoxical way. At first glimpse, there is no subjective effect, because everything, inside and outside the individual, speeds up equally. But, more subtly, speed-up produces an expansion of the cyber universe, because, as thought accelerates, more subjective time passes during the fixed (probably lightspeed) physical transit time of a message between a given pair of locations - so those fixed locations seem to grow farther apart. Also, as information storage is made continually more efficient through both denser utilization of matter and more efficient encodings, there will be increasingly more cyber-stuff between any two points. The effect may somewhat resemble the continuous-creation process in the old steady-state theory of the physical universe of Hoyle, Bondi and Gold, where hydrogen atoms appear just fast enough throughout the expanding cosmos to maintain a constant density. SCIENCE BEYOND THE ATMOSPHERE: THE HISTORY OF SPACE RESEARCH IN EUROPE
Arturo Russo, ed. Noordwijk, The Netherlands Jul. 1993 220 p Symposium held in Palermo, Italy, 5-7 Nov. 1992
(ESA-HSR-SPECIAL) Avail: CASI HC A10/MF A03

The papers included were prepared for a symposium held in Palermo in early November 1992. The aim of the symposium, organized in the framework of the ESA History Project, was to discuss critically the development of the scientific programs of ESRO and ESA by bringing together some of the main protagonists of the history of space research in Europe and a few historians working in the field. The symposium was sponsored by the University of Palermo, the Italian National Research Council and the European Space Agency. Topics covered include: Space science in ESRO and ESA; how space scientists and governments saw ESRO in the early 1960's; solar research in the early days of COPERS and ESRO; ionospheric research by rockets and satellites in Europe in the 1960's; the start of the space research in Sweden during the COPERS and early ESRO years; and from sounding rocket to small satellites, a way of complementing ESRO/ESA flight opportunities. The activities of the Laboratory of Space Technology in 1992 are described. The Laboratory is responsible for teaching space technology at the university. The main area in research is airborne and spaceborne remote sensing, including instrumentation, measurements, and development of geophysical inversion algorithms. Data from the ESA ERS-1 SAR was used in several projects, including remote sensing of sea ice, snow, and forests. In satellite technology, design and construction of our own satellite HUTSAT (Helsinki University of Technology Satellite) was started. In connection with the 22nd European Microwave Conference, the Laboratory of Space Technology organized a one-day Workshop on Microwaves in Environmental Monitoring. NTIS

HILL EQUATIONS FOR SATELLITE ORBIT DETERMINATION Thesis [DE VERGELIJKINGEN VAN HILL VOOR DE BEPALING VAN EEN SATELLIETBAAN]

R. G. vanCoevorden Nov. 1992 92 p In DUTCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-94-95374) Avail: CASI HC A05

Equations of motion using a periodical circular orbit are addressed. The orbital perturbations are given with respect to this moving triad. This set of equations, called the Hill equations, exists of three second order linear differential equations. They describe the problem in a first order approximation. Depending on the type of the disturbing forces, there exist different solutions of these equations. When there are no disturbing forces, the equations are called the homogeneous Hill equations, and only the initial values of the state vector can change the shape of the orbit. Disturbing forces which are more complex, can be transformed into Fourier series and then used in the equations to get an exact analytical solution of the approximated problem. By looking at the complete solution of the Hill equations, it can be seen that there are a few cases in which the solutions are not valid. The so called critical frequencies give a resonant effect on the orbital perturbations. These frequencies are the zero frequency and the once per revolution frequency. Resonant sources are for instance: drag, solar pressure, etc. A simple rendezvous problem, which describes the use of the homogeneous equations of motion, is discussed, some resonant sources are explained, and two examples of some relativistic effects are given. The cases in which the disturbing frequency is almost equal to a critical frequency are described. The amplitudes of the perturbations can grow very big in these so called near resonance cases. As a result of this work, the Hill equations can be said to be very good for educative purposes, because they give a very good view on the effects of disturbing forces on the orbit of a satellite. It should always be kept in mind that many simplifications are made when deriving the Hill equations. ESA

THE MODAL SOLUTION TO THE MOON'S ORBIT USING CANONICAL FLOQUET PERTURBATION THEORY M.S. Thesis

Kurt A. Vogel Dec. 1993 100 p
(AD-A273732; AFIT/GA/ENY/93D-9) Avail: CASI HC A05/MF A02

Using the restricted three body problem, the equations of motion (EOM) and Hamiltonian are computed for the moon's orbit in physical variables. A periodic orbit is found in the vicinity of the moon's orbit, and classical Floquet theory is applied to the periodic orbit to give stability information and the complete solution to the equations of variation. Floquet theory also supplies a transformation from physical variables to modal variables. This transformation to modal variables is made canonical by constraining the initial transformation matrix to be symplectic. Actual lunar data is used to calculate the modes for the real moon's orbit. Once satisfied that the moon's real-world modes are in (or near) the linear regime of the periodic orbit, the modal EOM are found by doing a perturbation expansion on the new modal Hamiltonian. The modal results from the real lunar orbit are compared with the modal EOM/expansion results. The modal expansion proves to be an accurate solution to the moon's orbit given enough expansion terms. The Space Exploration Initiative has generated a renewed interest in lunar mission planning. The lunar missions currently under study, unlike the Apollo missions, involve long stay times. Several lunar gravity models have been formulated, but mission planners do not have enough confidence in the proposed models to conduct detailed studies of missions with long stay times. In this report, a particular lunar gravitational model, the Ferrari 5 x 5 model, was chosen to determine the lifetimes for 100-km and 300-km perilune altitude, near-circular parking orbits. The need to analyze orbital lifetimes for a large number of initial orbital parameters was the motivation for the formulation of a simplified gravitational model from the original model. Using this model, orbital lifetimes were found to be heavily dependent on the initial conditions of the nearly circular orbits, particularly the initial inclination and argument of perilune. This selected model yielded lifetime predictions of less than 40 days for some orbits, and other orbits had lifetimes exceeding a year. Although inconsistencies and limitations are inherent in all existing lunar gravity models, primarily because of a lack of information about the far side of the moon, the methods presented in this analysis are suitable for incorporating the moon's nonspherical gravitational effects on the preliminary design level for future lunar mission planning. SYSTEM DESIGN ANALYSIS OF A LIGHTWEIGHT LASER SATELLITE TERMINAL M.S. Thesis

Brian C. Page Dec. 1993 81 p
(AD-A274033; AFIT/GSO/ENG/93D-03) Avail: CASI HC A05/MF A01

This study investigated the technological feasibility of a man-portable satellite laser communications system. Areas of interest were: an end-to-end system analysis on the communications link; evaluation of atmospheric effects; and evaluation of semiconductor lasers as the laser source. A literature search revealed that satellite laser communication research is primarily directed at intersatellite links. There have been some proposed systems for space-to-ground laser communications systems, but they all utilize large fixed ground stations. The focus of this research effort is directed at a small man-portable ground station capitalizing on recent advances in semiconductor laser devices. Baseline satellite communication systems were analyzed for both conventional radio frequency systems and a laser communication system. Modifications to the laser communications system were explored, and found to be feasible for some applications. Atmospheric effects were explored and are a major contributor to system degradation. Semiconductor laser sources were evaluated and are currently useful for some satellite laser communication applications. DTIC

A LARGE HIGH VACUUM, HIGH PUMPING SPEED SPACE SIMULATION CHAMBER FOR ELECTRIC PROPULSION

Stanley P. Grisnik and James E. Parkes (Sverdrup Technology, Inc., Brook Park, OH.) Jan. 1994 10 p Presented at the 23rd International Electric Propulsion Conference, Seattle, WA, 13-16 Sep. 1993; sponsored by AIAA, AIDAA, DGLR, and JSASS
(Contract NAS3-25266; RTOP 506-42-31)
(NASA-TM-106453; E-8080; NAS 1.15:106453; IEPC-93-151) Avail: CASI HC A02/MF A01

Testing high power electric propulsion devices poses unique requirements on space simulation facilities. Very high pumping speeds are required to maintain high vacuum levels while handling large volumes of exhaust products. These pumping speeds are significantly higher than those available in most existing vacuum facilities. There is also a requirement for relatively large vacuum chamber dimensions to minimize facility wall/thruster plume interactions and to accommodate far field plume diagnostic measurements. A 4.57 m (15 ft) diameter by 19.2 m (63 ft) long vacuum chamber at

NASA Lewis Research Center is described. The chamber utilizes oil diffusion pumps in combination with cryopanels to achieve high vacuum pumping speeds at high vacuum levels. The facility is computer controlled for all phases of operation from start-up, through testing, to shutdown. The computer control system increases the utilization of the facility and reduces the manpower requirements needed for facility operations.

HYDROGEN-OXYGEN TORCH IGNITOR

George A. Repas Mar. 1994 17 p
(RTOP 584-03-21)
(NASA-TM-106493; E-8480; NAS 1.15:106493) Avail: CASI HC A03/MF A01

The hydrogen-oxygen torch igniter described herein has been successfully used for many years at various NASA Lewis Research Center rocket test facilities to provide ignition for rocket engine research hardware. This igniter is inexpensive, simple to operate, and has demonstrated very good reliability. It has been used as an ignition source for rocket engines that utilized a variety of propellant combinations; some of these engines developed up to 40,000 lb of thrust.

MULTIDISCIPLINARY AEROELASTIC ANALYSIS OF A GENERIC HYPERSONIC VEHICLE

K. K. Gupta and K. L. Petersen Washington Oct. 1993 13 p
Presented at the AIAA 5th International Aerospace Planes Conference, Munich, Germany, 30 Nov. - 3 Dec. 1993
(RTOP 505-70-00)
(NASA-TM-4544; H-1956; NAS 1.15:4544; AIAA Paper 93-5028) Avail: CASI HC A03/MF A01

This paper presents details of a flutter and stability analysis of aerospace structures such as hypersonic vehicles. Both structural and aerodynamic domains are discretized by the common finite element technique. A vibration analysis is first performed by the STARS code employing a block Lanczos solution scheme. This is followed by the generation of a linear aerodynamic grid for subsequent linear flutter analysis within subsonic and supersonic regimes of the flight envelope; the doublet lattice and constant pressure techniques are employed to generate the unsteady aerodynamic forces. Flutter analysis is then performed for several representative flight points. The nonlinear flutter solution is effected by first implementing a CFD solution of the entire vehicle. Thus, a 3-D unstructured grid for the entire flow domain is generated by a moving front technique. A finite element Euler solution is then implemented employing a quasi-implicit as well as an explicit solution scheme. A novel multidisciplinary analysis is next effected that employs modal and aerodynamic data to yield aerodynamic damping characteristics. Such analyses are performed for a number of flight points to yield a large set of pertinent data that define flight flutter characteristics of the vehicle. This paper outlines the finite-element-based integrated analysis procedures in detail, which is followed by the results of numerical analyses of flight flutter simulation.

A COMPARISON OF USERS' AND PROVIDERS' PERCEPTIONS OF CRITICAL SPACELIFT VEHICLE CHARACTERISTICS AND CAPABILITIES M.S. Thesis

Dawson S. Oslund and Mark M. Shafer Sep. 1993 134 p
(AD-A273907; AFIT/GLM/LAR/93S-32) Avail: CASI HC A07/MF A02

This study compares spacelift vehicle users' and providers' perceptions of critical spacelift vehicle characteristics and capabilities. The researchers conducted a mail survey of military, commercial, and civil spacelift vehicle users and providers to determine a criticality rating for each of the 22 characteristics and capabilities identified through a literature review. Primary results of the study indicate: the three most critical characteristics and capabilities are reliability, launch cost, and resilience; the three least critical characteristics and capabilities are man-rateable, reusability, and gross lift-off weight; only launch cost has a significantly different mean criticality rating among spacelift vehicle users and providers; and 13 of the 22 characteristics and capabilities have significantly different mean criticality ratings between military and commercial respondents. The researchers conclude that differences between users' and providers' perceptions are inconsequential, but further study of military and commercial perceptions is necessary.

APPLICATION OF SPACE SHUTTLE PROJECT HERCULES IMAGERY IN THE INVESTIGATION OF SHIP CLOUD TRACKS M.S. Thesis
Larry E. Whitmeyer Sep. 1993 141 p
(AD-A274923) Avail: CASI HC A07/MF A02

An assessment is made as to the utility obtained via the Project HERCULES electronic still camera system, utilized onboard the Space Shuttle, toward the MAST Space Test Program investigation of ship-induced cloud tracks. Project HERCULES and MAST concepts are described. A detailed discussion is presented of the integration requirements, mission conduct, and payload support procedures involved in using the HERCULES system during the STS-56 mission to image potential shiptrack areas and Naval-related sites. Five HERCULES imagery cases are analyze with feature measurements. Alternate camera systems are described, and then compared with the HERCULES system. Recommendations are made for the MAST payload. Although utility is seen in the geolocation and digital format offered by HERCULES images, the present configuration permits only limited use in the shiptrack and Naval-related application. However, a firm procedural knowledge-base has been established for the MAST experiment. DTIC

RISKS AND ISSUES IN FIRE SAFETY ON THE SPACE STATION
Robert Friedman Dec. 1993 8 p Presented at the Probabilistic Safety and Management Conference, San Diego, CA, 21-25 Mar. 1994; sponsored by the Society for Risk Analysis
(RTOP 323-44-03)
(NASA-TM-106430; E-8272; NAS 1.15:106430) Avail: CASI HC A02/MF A01

A fire in the inhabited portion of a spacecraft is a greatly feared hazard, but fire protection in space operations is complicated by two factors. First, the spacecraft cabin is an enclosed volume, which limits the resources for fire fighting and the options for crew escape. Second, an orbiting spacecraft experiences a balance of forces, creating a near-zero-gravity (microgravity) environment that profoundly affects the characteristics of fire initiation, spread, and suppression. The current Shuttle Orbiter is protected by a fire-detection and suppression system whose requirements are derived of necessity from accepted terrestrial and aircraft standards. While experience has shown that Shuttle fire safety is adequate, designers recognize that improved systems to respond specifically to microgravity fire characteristics are highly desirable. Innovative technology is particularly advisable for the Space Station, a forthcoming space community with a complex configuration and long-duration orbital missions, in which the effectiveness of current fire-protection systems is unpredictable. The development of risk assessments to evaluate the probabilities and consequences of fire incidents in spacecraft are briefly reviewed. It further discusses the important unresolved issues and needs for improved fire safety in the Space Station, including those of material selection, spacecraft atmospheres, fire detection, fire suppression, and post-fire restoration. DEBRIS/ICE/TPS ASSESSMENT AND INTEGRATED PHOTOGRAPHIC ANALYSIS FOR SHUTTLE MISSION STS-60 Final Report, 1-14 Feb. 1994
Gregory N. Katnik, Barry C. Bowen, J. Bradley Davis, Jorge E. Rivera, and Robert F. Speece Mar. 1994 110 p Original contains color illustrations
(NASA-TM-109193; NAS 1.15:109193) Avail: CASI HC A06/MF A02; 44 functional color pages

A debris/ice/thermal protection system (TPS) assessment and integrated photographic analysis was conducted for Shuttle mission STS-60. Debris inspections of the flight elements and launch pad were performed before and after launch. Icing conditions on the External Tank were assessed by the use of computer programs, nomographs, and infrared scanner data during cryogenic loading of the vehicle followed by on-pad visual inspection. High speed photography of the launch was analyzed to identify ice/debris sources and evaluate potential vehicle damage and/or in-flight anomalies. This report documents the ice/debris/TPS conditions and integrated photographic analysis of Shuttle mission STS-60, and the resulting effect on the Space Shuttle Program. Author

ARTEMIS COMMON LUNAR LANDER. PHASE 2: STUDY RESULTS FOR EXTERNAL REVIEW
10 Mar. 1992 131 p
(NASA-TM-109699; NAS 1.15:109699) Avail: CASI HC A07/MF A02

The purpose of the Artemis Program is to gather vital reconnaissance data by conducting robotic exploration missions to the lunar surface both prior to and concurrent with human exploration missions. The Artemis Program includes rapid, near-term development of a variety of small experimental and operational payloads, provides a low-cost capability to deliver these payloads to any location on the lunar surface, and supports the analysis of the data returned. The Artemis Program will improve the understanding of lunar geosciences, demonstrate the Moon's unique capability as an astronomical platform to study the universe, and to conduct scientific and technology development experiments, and will prepare for,

enhance, and complement human mission The Artemis Common Lunar Lander Phase 2 Study results for external review are included.

STS-57 SPACE SHUTTLE MISSION REPORT
Robert W. Fricke, Jr. Aug. 1993 52 p Sponsored by NASA. Johnson Space Center
(NASA-CR-195739; NAS 1.26:195739; JSC-08285; NSTS-08285) Avail: CASI HC A04/MF A01

The STS-57 Space Shuttle Program Mission Report provides a summary of the Payloads, as well as the Orbiter, External Tank (ET), Solid Rocket Booster (SRB), Redesigned Solid Rocket Motor (RSRM), and the Space Shuttle main engine (SSME) systems performance during the fifty-sixth flight of the Space Shuttle Program and fourth flight of the Orbiter vehicle Endeavour (OV-105). In addition to the Orbiter, the flight vehicle consisted of an ET (ET-58); three SSME's which were designated as serial numbers 2019, 2034, and 2017 in positions 1, 2, and 3, respectively; and two SRB's which were designated BI-059. The lightweight RSRM's that were installed in each SRB were designated as 360L032A for the left SRB and 360W032B for the right SRB. The STS-57 Space Shuttle Program Mission Report fulfills the Space Shuttle Program requirement, as documented in NSTS 07700, Volume 8, Appendix E. That document states that each major organizational element supporting the Program will report the results of their hardware evaluation and mission performance plus identify all related in-flight anomalies. The Telemedicine Spacebridge Demonstration Project is a joint U.S./Russian program whose purpose is to further the application of telemedicine both internationally, domestically, and in space. The system has been set up to use a Russian satellite over the Atlantic Ocean and a U.S. domestic satellite to allow physicians a two-way video and audio link between various sites of medical centers in the United States and the Central Hospital in Moscow, Russia. This paper contains a description of the project background, the Spacebridge system, the individual pieces of the system, and the operational experience gained thus far in the project.

TELECOMMAND DECODER SPECIFICATION
Sep. 1993 115 p
(ISSN 0379-4059)
(ESA-PSS-04-151-Issue-1; ETN-94-95457) Copyright Avail: CASI HC A06/MF A02

The purpose of the specification is to establish uniform requirements for the implementation of spacecraft telecommand systems to be flown onboard ESA spacecraft. The ESA telecommand concept embraces multiple layers of data communication protocols which are specified in two documents: the radio frequency and modulation standard; and the packet telecommand standard. The telecommand subsystem requirements, which apply to free flying spacecraft, are overviewed. The physical layer document provides the information required for a broader view of the overall telecommand system. Particular attention is given to the interference between the physical and the coding layers at the receiving end and the actions at the receiving end. Specifications concerning the coding, the functions of the transfer, the authentication, and the command pulse distribution unit are included. The requirements on telemetry reporting are summarized. Interface functional design specifications are given. ESA

HUMAN VISUAL SYSTEM ENHANCEMENT OF RECONSTRUCTED SATELLITE IMAGES M.S. Thesis
James E. Treleaven 15 Dec. 1993 72 p
(AD-A273867; AFIT/GEO/ENP/93D-04) Avail: CASI HC A04/MF A01

The enhancement of satellite images was investigated. The goal was to develop and test a suite of image enhancement software routines to improve the quality of reconstructed images for the human visual system. The primary focus was to enhance satellite features. Enhancement was accomplished in both the spatial domain and the frequency domain. In the spatial domain, routines were developed to enhance image contrast and edges. In the frequency domain, a routine was developed using research into the human visual system. The transfer function of the human visual system was used to develop a filter for frequency domain enhancement. A data set of images was developed using software to simulate the image degradation caused by atmospheric turbulence and the randomness of the image measurement process. The parameters varied in the simulation were atmospheric coherence diameter and total photon count. The routines were applied to this data set and the results were evaluated by various image fidelity criteria. All enhancement routines provided enhancement dependent upon the parameters of the data set simulation. Contrast enhancement worked well when photon count was low. Edge enhancement worked well when photon count was high. The frequency domain filter worked well always. DTIC

A COMPARISON OF THREE APPROXIMATE MATHEMATICAL MODELS FOR THE GRAVITY GRADIENT STABILIZED SATELLITE M.S. Thesis
R. K. Adams Dec. 1993 138 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273832; AFIT/GA/ENY/93D-1) Avail: CASI HC A07

This study compared an exact nonlinear model for the gravity gradient satellite to the two classical approximate models: the linearized model; and the truncated nonlinear model. These two models are typically used for analysis of the motion and stability of gravity gradient satellites. Rigid body dynamics using molecular mass models and circular orbits were assumed to isolate the comparison to the different models. The complete equations of motion of the exact nonlinear model resulted in more complex motions about the classical points of relative equilibria. DTIC

PROTOTYPE SPACE FABRICATION PLATFORM M.S. Thesis
James A. Bessel, James M. Ceney, David M. Crean, Edward A. Ingham, and David J. Pabst Dec. 1993 497 p
(AD-A273904; AFIT/GSE/ENY/93D-1) Avail: CASI HC A21/MF A04

Current plans for constructing large structures in space entail fabricating the primary components, such as truss segments, on the ground and assembling them in space. This process requires an exorbitant number of support missions, and methods to minimize the number must be considered. Whenever the space shuttle is launched, its external tank is jettisoned and destroyed prior to reaching orbit. This aerospace grade aluminum structure can be carried into orbit and utilized extrusively. The Prototype Space Fabrication Platform (SFP) fabricates aluminum materials, reduced from external tanks, into functional trusses. The trusses are strong and can be used as the primary components for future structures in space. The fabrication process produces a continuous truss allowing the end user to determine the length. The SFP can fabricate the same amount of truss from one external tank as four dedicated shuttle missions can deliver in the cargo bay. The SFP utilizes electrodynamic propulsion, via shielded coils, for maneuvering. The novel propulsion system facilitates a versatile payload transportation and delivery capability. The SFP can continuously track a target from all directions. The tracking system is ideal for docking since plume impingement is not a concern. With the assistance of remote manipulators, the SFP can deliver a payload in a wide variety of orientations. Under most conditions, the remote manipulator and maneuvering commands originate from ground workstations. Required manned presence is greatly reduced, and the time when the space shuttle is off station is effectively utilized. The logistical complications, currently inhibiting advancement in space, can be eliminated. DTIC

AUTOMATING SATELLITE RANGE SCHEDULING M.S. Thesis
S. M. Schalck Dec. 1993 167 p
(AD-A273829; AFIT/GSO/ENS/93D-14) Avail: CASI HC A08/MF A02

The objective was to develop a computer based satellite range scheduling (SRS) algorithm to create a 24 hour satellite support schedule. The algorithm's goal was to schedule as many satellite support requests as possible. An iterative heuristic approach was used to schedule satellite support requests in three successive subproblems. The first subproblem involves scheduling low altitude satellite support requests using a mixed integer programming approach. The next two subproblems each involve scheduling 12 hour blocks of medium and high altitude satellite support requests, again using a mixed integer programming approach. Fourteen 24 hour schedules were generated using actual data with encouraging results. At least 95 percent of the satellite support requests were scheduled for each day. These results are in-line with results obtained by range schedulers and previous studies. Because of the promising results, this algorithm may be used to automate a portion of the satellite range scheduling problem. DTIC

MODAL CONTROL OF A SATELLITE IN AN UNSTABLE PERIODIC ORBIT ABOUT THE EARTH-SUN INTERIOR LAGRANGE POINT M.S. Thesis
Douglas J. Hopper Dec. 1993 95 p
(AD-A273707; AFIT/GA/ENY/93D-3) Avail: CASI HC A05/MF A01

A periodic 'halo' orbit which exists about the interior Lagrange point for the Earth-sun system was decomposed using Floquet theory into modal variables, which are dynamically decoupled subspaces for the six degree of freedom system. Modal control consisted of evaluating the diverging mode and maneuvering to counteract its divergence. In the unperturbed system, this was successful. Control costs were low, and the significance is that the controller did nothing to suppress modes that were oscillatory or converging. The effect of the moon's motion allowed the scheme to operate with reasonable control costs, but the effect of eccentricity caused divergence in spite of the controller. DTIC

DESIGN ANALYSIS OF A COMBINED OPTICAL/LADAR DEEP-SPACE SURVEILLANCE SATELLITE M.S. Thesis
Bradley K. Fournier Dec. 1993 95 p
(AD-A274040; AFIT/GSO/Eng/93D-1) Avail: CASI HC A05/MF A01

This research determines the performance requirements of a combined optical/LADAR space-based system in order to detect and track deep-space satellites from a near-earth orbit satellite. The research derives the necessary equations to compare both direct and heterodyne detection techniques. The selection of the candidate laser systems is based on current space developed LADAR technology. The selection of the detector, detector size, and optic size are determined in order to maximize the signal-to-noise ratio. The analysis includes the effects of beam truncation, obscuration, pixel geometry, and background radiance. The results indicate that the direct detection technique with a GaA1As semiconductor laser and a charge-couple device detector provided the best signal-to-noise ratio for the range selected. In addition, the visible detection capability of the smallest entrance pupil system is compared with that of GEODSS. For the parameters chosen, the results indicate that this system should, on average, be able to detect objects of smaller size than GEODSS. DTIC

A VIRTUAL ENVIRONMENT FOR SATELLITE MODELING AND ORBITAL ANALYSIS IN A DISTRIBUTED INTERACTIVE SIMULATION M.S. Thesis
Andrea A. Kunz Dec. 1993 98 p
(AD-A274114; AFIT/GCS/ENG/93D-14) Avail: CASI HC A05/MF A02

In response to the need for a more realistic, interactive, and immersive space simulation system, the Joint National Intelligence Defense Staff (JNIDS) has sponsored the development of the Satellite Modeler at the Air Force Institute of Technology (AFIT). The Satellite Modeler (SM) is a virtual environment (VE) application that allows analyst-users to enter a virtual near-Earth space environment and visualize realistic satellite models performing accurate orbital motion. The Satellite Modeler provides manipulation functions that allow a user to interact with multiple satellite models and satellite constellations. The system affords the user multiple vantage points within the environment to view satellites in orbit. It also functions as a network actor in a distributed simulation environment. The Satellite Modeler achieves accurate physical modeling of satellite motion by using the North American Air Defense (NORAD) Command SGP4 orbital model and associated orbital elements for satellites currently in orbit. System functionality is realized within an object-oriented framework and accessible through a graphical user interface (GUI). This thesis is the second of a three-year effort to create a three dimensional virtual environment for modeling and manipulating satellite objects. DTIC

SATELLITE ATTITUDE DETERMINATION USING LINEAR COMBINATION OF MODELS M.S. Thesis
Martin S. Chin Dec. 1993 96 p
(AD-A274082; AFIT/GE-93D-05) Avail: CASI HC A05/MF A01

In satellite analysis, it is often necessary to determine the attitude of

a satellite from a two dimensional image of the satellite. This thesis describes work performed to determine the attitude of a satellite relative to a reference position. The attitude is described in terms of the scaling, rotation, and translation of the reference that will result in a pose that can be projected to form the image of interest. The techniques used are based on finding coefficients for the linear combination of basis images and decomposition of a composite transformation matrix. The methods were initially modeled in Mathematica and applied to simple objects, then implemented on a Silicon Graphics Workstation and applied to a model of an actual satellite. An accurate estimate of the pose of a satellite in a 2D image can be estimated based on the information contained in the image and a 3D model of the satellite or a set of images of the satellite at known orientations. Results of a performance analysis of the SGI implementation, a user's guide, source code in Mathematica and a software reference are included.

USER'S GUIDE FOR THE THERMAL ANALYST'S HELP DESK EXPERT SYSTEM
Rachel A. Ormsby Jan. 1994 63 p
(Contract NAS1-19000; RTOP 477-50-00-01)
(NASA-CR-194885; NAS 1.26:194885) Avail: CASI HC A04/MF A01

A guide for users of the Thermal Analyst's Help Desk is provided. Help Desk is an expert system that runs on a DOS based personal computer and operates within the EXSYS expert system shell. Help Desk is an analysis tool designed to provide users having various degrees of experience with the capability to determine first approximations of thermal capacity for spacecraft and instruments. The five analyses supported in Help Desk are: surface area required for a radiating surface, equilibrium temperature of a surface, enclosure temperature and heat loads for a defined position in orbit, enclosure temperature and heat loads over a complete orbit, and selection of appropriate surface properties. The two geometries supported by Help Desk are a single flat plate and a rectangular box enclosure.

MOUNTING OF SSM'S [SSM-PEILIEN KIINNITYS]
Juha Pohjonen Jan. 1993 25 p In FINNISH
(ISSN 1235-0605)
(VTT-TIED-1442; ISBN-951-38-4335-1; ETN-94-95265) Copyright Avail: CASI HC A03/MF A01

A step by step description of how to mount SSM's (Second Surface Mirrors) on the space instruments is presented. Experiences of the first SSM implementation are described. The Soho satellite has in its payload, an instrument ERNE, which has a radiation wing covered with SSM. SSM's are easy to use and reliable for thermal control design to space instruments. SSM's have a very small alpha(sub s) compared to the epsilon(sub n). The radiation from the Sun is reflected and at the same time the heat generated by the instrument is emitted to the space. This gives a good opportunity to tune the thermal control design according to the temperature.

STRUCTURAL EVALUATION OF CONCEPTS FOR A SOLAR ENERGY CONCENTRATOR FOR SPACE STATION ADVANCED DEVELOPMENT PROGRAM
Winfred S. Kenner and Marvin D. Rhodes Feb. 1994 32 p
(RTOP 506-43-41-02)
(NASA-TP-3375; L-17239; NAS 1.60:3375) Avail: CASI HC A03/MF A01

Solar dynamic power systems have a higher thermodynamic efficiency than conventional photovoltaic systems; therefore they are attractive for long-term space missions with high electrical power demands. In an investigation conducted in support of a preliminary concept for Space Station Freedom, an approach for a solar dynamic power system was developed and a number of the components for the solar concentrator were fabricated for experimental evaluation. The concentrator consists of hexagonal panels comprised of triangular reflective facets which are supported by a truss. Structural analyses of the solar concentrator and the support truss were conducted using finite-element models. A number of potential component failure scenarios were postulated and the resulting structural performance was assessed. The solar concentrator and support truss were found to be adequate to meet a 1.0-Hz structural dynamics design requirement in pristine condition. However, for some of the simulated component failure conditions, the fundamental frequency dropped below the 1.0-Hz design requirement. As a result, two alternative concepts were developed and assessed. One concept incorporated a tetrahedral ring truss support for the hexagonal panels: the second incorporated a full tetrahedral truss support for the panels. The results indicate that significant improvements in stiffness can be obtained by attaching the panels to a tetrahedral truss, and that this concentrator and support truss will meet the 1.0-Hz design requirement with any of the simulated failure conditions.

SUBSTRUCTURE SYNTHESIS METHODS FOR VISCOELASTIC STRUCTURES
Duan Qian Sep. 1993 199 p
(ISSN 0082-5255)
(UTIAS-349; CTN-94-61012) Copyright Avail: CASI HC A09/MF A03

Viscoelastic damping models are necessary for accurate dynamic analysis of flexible aerospace structures. The method of substructure synthesis is extended to systems with general linear viscoelastic damping. The stationary variational principles for discrete symmetric and nonsymmetric viscoelastic systems are first developed in parallel for the time, Laplace, and frequency domain. The corresponding substructure synthesis methods are then formulated. On the basis of the Rayleigh-Ritz method, each substructure is represented by a set of admissible trial vectors. Real trial vectors, such as eigenvectors and Lanczos vectors of the corresponding undamped substructure as well as Ritz vectors obtained by spatial discretization of simple functions, are recommended. The geometric compatibility between substructures can be approximated by a weighted residual method, and the traditional state space formulation is avoided. The effort involved in the reduction process is almost independent of the complexity of viscoelastic models. Beam and plate examples are presented to illustrate the effectiveness of the substructure synthesis method in terms of reducing the size of final equations to obtain accurate solutions of eigenvalues, frequency responses, and transient responses for viscoelastic symmetric systems.

A SURVEY OF UNCONTROLLED SATELLITE REENTRY AND IMPACT PREDICTION M.S. Thesis
Brian D. Neuenfeldt and William K. Henderson 23 Sep. 1993 268 p
Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A274903) Avail: CASI HC A12

The primary goal of this thesis is to identify the 'state of the art' in orbit decay induced uncontrolled reentry/impact prediction methods, with an emphasis on the physics of the final few revolutions to impact. This was accomplished through a comprehensive literature survey from the 1950's to the present of unclassified military and civil databases. The results of the survey show that the current U.S. and international reentry/impact prediction methodologies are based on analysis which is over 30 years old. Of the various 'extensions' to the current reentry theory, of which the NORAD method is recognized as the international standard, there does not appear to be any one method which is singularly superior to the others. It has also been shown that numerous reentry investigations made simplifying assumptions due to insufficient data needed to accurately model reentry and also because of computing limitations of their day. Also, current deterministic dynamic models appear to inadequately describe the actual uncontrolled reentry process, due to a lack of observational data, uncertainty in determining aerodynamic coefficients, atmospheric density, and point mass modeling where changes in vehicle configuration, attitude, and lift are neglected. Stochastic and statistical methods could be applied to the current methodology to better analyze the various uncertainties, which could help to improve the overall predicted impact time and location; however, further research into these methods along with the physics of uncontrolled reentry is necessary. The protection scheme developed for long duration space platforms relies primarily upon placing thin metal plates or 'bumpers' around flight critical components. The effectiveness of this system is highly dependent upon its ability to break up and redistribute the momentum of any particle which might otherwise strike the outer surface of the spacecraft. Therefore it is of critical importance to design the bumpers such that maximum dispersion of momentum is achieved. This report is devoted to an in-depth study into the design and development of a laboratory instrument which would permit the in-situ monitoring of the momentum distribution as the impact event occurs. A series of four designs were developed, constructed and tested culminating with the working instrument which is currently in use. Each design was individually tested using the Space Environmental Effects Facility (SEEF) at the Marshall Space Flight Center in Huntsville, Alabama. Along with the development of the device, an experimental procedure was developed to assist in the investigation of various bumper materials and designs at the SEEF. Preliminary results were used to compute data which otherwise were not experimentally obtainable. These results were shown to be in relative agreement with previously obtained values derived through other methods. The results of this investigation indicated that momentum distribution could in fact be measured in-situ as the impact event occurred thus giving a more accurate determination of the effects of experimental parameters on the momentum spread. Data produced by the instrument indicated a Gaussian-type momentum distribution. A second apparatus was developed and it was placed before the shield in the line of travel utilized a plate to collect impact debris scattered backwards. This plate had a passage hole in the center to allow the particle to travel through it and impact the proposed shield material. Applying the law of conservation of angular momentum a backward momentum vector was determined from the angular velocity of the plate. The forward scattered and backward scattered momentum values were then analyzed to judge the distribution of debris. Loss of momentum was attributed to the inaccuracies of the means of measurement. Assumptions of symmetrical debris for the forward and backward scattered directions also contributed to this loss. Author

We describe a novel, lightweight x-ray burst detector that can be embedded in a satellite structure, thus forming a 'smart skin,' which has minimal impact on the host satellite. The design is based on two types of optical fibers coupled to photodiodes. The first is a scintillating fiber, which gives a fast signal for timing. The second is a germanium-doped silica fiber, which darkens for a few milliseconds when irradiated with a burst of x rays. The resulting slow signal is used to discriminate against electrostatic discharges. The coincidence of a fast signal from the scintillating fiber with a slow signal from the darkening fiber is the signature of an x-ray burst. The response is linear at low doses and becomes nonlinear at high doses. We have two techniques to test the instrument in a space experiment scheduled for 1994. First, a small, space-qualified flash x-ray unit can illuminate the fibers. Second, we can detect space background radiation. The cumulative dose will be monitored by RADFET dosimeters. Future work on embedding the fibers and the electronics as Application Specific Integrated Circuits (ASIC's) in the spacecraft skin could lead to use of these detectors on many satellites. DOE

DYNAMICS AND ROBUST CONTROL FOR UNCERTAIN FLEXIBLE SPACE SYSTEMS
L. C. Gadelha DeSouza (Cranfield Inst. of Tech., Bedford, England.) Sep. 1992 261 p
(INPE-5510-TAE/020) Avail: CASI HC A12/MF A03

The uncertain nature of the dynamics of flexible space structures makes sensitivity and robustness questions of great importance when designing control systems, mainly, because nominal performance and robust stability are conflicting objectives in control systems design. A coupled rigid body/flexible structural dynamics model of the MB-1 Space Station configuration is developed and employed to investigate such important issues arising in robust control design. Selection of a reduced order model plays an important role in flexible spacecraft control leading to expected errors between the design model and the actual system. On the other hand, the inability of ground testing of large flexible structure for model verification leads to structural parameters which can possess appreciable errors. An asymptotic Linear Quadratic Gaussian (LQG) design procedure based on a modified version of the Parameter Robust Linear Quadratic Gaussian (PRLQG) approach is developed for designing a robust controller that accounts for unmodelled dynamics and parameter uncertainty for multi-input multi-output systems. The unmodelled dynamics are assumed to be characterized as a single block dynamic uncertainty at a point in the closed-loop system. Plant parameter variations are represented as an internal feedback loop via the input-output decomposition. A direct structural relationship between parameter uncertainties and the weighting matrices in the design of the LQG controller is exploited. This robust control design procedure is then applied to design a robust controller for attitude control and vibration suppression of the MB-1 Space Station model taking into account this mixed uncertainty model. This yields considerable improvement in robustness with respect to parameter variation without affecting the level of nominal performance and robustness with respect to unmodelled dynamics achieved. Extensive control simulations have shown that even under severe dynamic initial conditions the controller was able to impose quick convergence properties to the system. Author

SPACE PROJECTS: ASTROPHYSICS FACILITY PROGRAM CONTAINS COST AND TECHNICAL RISKS. REPORT TO CONGRESSIONAL REQUESTERS
David R. Warren 28 Jan. 1994 16 p
(GAO/NSIAD-94-80; B-255776) Avail: CASI HC A03/MF A01; GAO, P.O. Box 6015, Gaithersburg, MD 20877 HC

NASA is developing the Advanced X-ray Astrophysics Facility (AXAF) to be one of the mainstays of this nation's space science program during the next decade. It is to be used to investigate important questions such as the age and origin of the universe. The status of the 1992 redesigned AXAF program is reviewed to assess the reasonableness of NASA's estimate of program costs and to determine the extent to which the redesign will provide scientific returns comparable to the original program. It is recognized that a recent congressional direction may affect a portion of this program, but the cost and technical impacts of that decision are uncertain at this time. However, the results of the work in other segments of the program are still relevant. Derived from text

A handbook which provides general engineering guidelines suitable for project groups engaged in the design of spacecraft required to operate in regions of space where they will be exposed to significant doses of radiation is presented. The charged particle environment in geomagnetospheric space, and the physics of radiation effects on solid state devices and materials (including ionization effects, single event upsets and bulk displacement damage) in all the designs of devices likely to be used in spacecraft are discussed. Methods of assessing the impact of these effects are given, including procedures for calculating the orbital radiation environment, dose depth curves within electronic enclosures, and the end of life degradation of devices and circuits. While no rigid procedures for handling these problems can be set out, special attention is given to methods of alleviating the problems presented. These methods cover tradeoff studies of orbit versus shield weight, layout rules for spacecraft, the use of redundancy and housekeeping dosimetry, device selection, device verification, and the design of radiation tolerant circuits. DEVELOPMENT AND APPLICATION OF CONTAMINATION TECHNOLOGY FOR MSFC MANAGED SPACE SYSTEMS Annual Progress Report, 10 Dec. 1992 - 10 Dec. 1993

1993 93 p Prepared in cooperation with Science Applications International Corp., Huntsville, AL
(Contract NAS8-39244)
(NASA-CR-193934; NAS 1.26:193934) Avail: CASI HC A05/MF A01

The second annual report on the development and application of contamination technology for MSFC managed space systems covering the period from 10 Dec. 1992 to 10 Dec. 1993 is presented. During this time period, studies were concluded which proved that in-process corrosion protection is not required during Redesigned Solid Rocket Motor (RSRM) case processing. Also completed were a series of tests evaluating the effects of environmental exposure and contamination on 2219-T87 aluminum (Space Shuttle External Tank) OSEE response and bonding properties. Correlations were developed between OSEE response, contamination type/level, and primer adhesion. The results showed that the wet tape and water break free tests currently employed during ET processing may not detect bond affecting levels of some potential contaminants; however, the contaminants were detected with OSEE analysis. Finally, exposure/contamination studies were initiated with HP9-4-30 steel. HP9-4-30 was selected for evaluation because it represents a class of metals commom to MSFC managed space flight systems which are less prone to oxidation than D6AC steel or aluminum. THE TMIS LIFE-CYCLE PROCESS DOCUMENT, REVISION A

Nov. 1991 42 p
(NASA-TM-109698; NAS 1.15:109698; SSP-30542-Rev-A) Avail: CASI HC A03/MF A01

The Technical and Management Information System (TMIS) Life-Cycle Process Document describes the processes that shall be followed in the definition, design, development, test, deployment, and operation of all TMIS products and data base applications. This document is a roll out of TMIS Standards Document (SSP 30546). The purpose of this document is to define the life cycle methodology that the developers of all products and data base applications and any subsequent modifications shall follow. Included in this methodology are descriptions of the tasks, deliverables, reviews, and approvals that are required before a product or data base application is accepted in the TMIS environment. A PARAMETRIC SENSITIVITY STUDY FOR SINGLE-STAGE-TO-ORBIT HYPERSONIC VEHICLES USING TRAJECTORY OPTIMIZATION

T. Alan Lovell and D. K. Schmidt 21 Mar. 1994 38 p
(Grant NAG1-1540)
(NASA-CR-195703; NAS 1.26:195703) Avail: CASI HC A03/MF A01

The class of hypersonic vehicle configurations with single stage-to-orbit (SSTO) capability reflect highly integrated airframe and propulsion systems. These designs are also known to exhibit a large degree of interaction between the airframe and engine dynamics. Consequently, even simplified hypersonic models are characterized by tightly coupled nonlinear equations of motion. In addition, hypersonic SSTO vehicles present a major system design challenge; the vehicle's overall mission performance is a function of its subsystem efficiencies including structural, aerodynamic, propulsive, and operational. Further, all subsystem efficiencies are interrelated, hence, independent optimization of the subsystems is not likely to lead to an optimum design. Thus, it is desired to know the effect of various subsystem efficiencies on overall mission performance. For the purposes of this analysis, mission performance will be measured in terms of the payload weight inserted into orbit. In this report, a trajectory optimization problem is formulated for a generic hypersonic lifting body for a specified orbit-injection mission. A solution method is outlined, and results are detailed for the generic vehicle, referred to as the baseline model. After evaluating the performance of the baseline model, a sensitivity study is presented to determine the effect of various subsystem efficiencies on mission performance. This consists of performing a parametric analysis of the basic design parameters, generating a matrix of configurations, and determining the mission performance of each configuration. Also, the performance loss due to constraining the total head load experienced by the vehicle is evaluated. The key results from this analysis include the formulation of the sizing problem for this vehicle class using trajectory optimization, characteristics of the optimal trajectories, and the subsystem design sensitivities. AN ANALYSIS OF THE LOADS APPLIED TO A HEAVY SPACE STATION RACK DURING TRANSLATION AND ROTATION TASKS

Lara E. Stoycos (Lockheed Engineering and Sciences Co., Houston, TX.) and Glenn K. Klute Feb. 1994 29 p
(NASA-TM-104790; S-760; NAS 1.15:104790) Avail: CASI HC A03/MF A01

To prepare for Space Station Alpha's on-orbit assembly, maintenance, and resupply, NASA requires information about the crew members' ability to move heavy masses on orbit. Ease of movement in microgravity and orbiter stay time constraints may change the Space Station equipment and outfitting design requirements. Therefore, the time and effort required to perform a particular task and how and where the forces and torque should be applied become critical in evaluating the design effort. Thus, the three main objectives of this investigation were to: (1) quantify variables such as force and torque as they relate to heavy mass handling techniques; (2) predict the time required to perform heavy mass handling tasks; and (3) note any differences between males and females in their ability to manipulate a heavy mass. AN APPROXIMATE SOLUTION FOR THE SPINUP DYNAMICS OF NEAR AXISYMMETRIC AXIAL GYROSTATS USING THE METHOD OF MULTIPLE SCALES M.S. Thesis
Stewart J. Kowall Dec. 1993 125 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273723; AFIT/GA/ENY/93D-5) Avail: CASI HC A06

Approximate solutions for the spinup of a near axisymmetric gyrostat are derived using the straightforward expansion method and the method of multiple scales. Two method of multiple scale solutions are presented. The first is derived using cartesian coordinates while the second is derived using cylindrical coordinates. The multiple scales solutions are compared to numerically integrated results for oblate and prolate configurations. A comparison for flat spin recovery is also accomplished. Excellent results are obtained for oblate configurations. Trajectory separatrix crossings hindered the results for prolate configurations and flat spin recoveries.

The Path Length Distribution method is used to model the performance of the dosimeter instruments used aboard the DMSP and CRRES satellites. The Monte Carlo methods used to compute the path length distributions for the isotropic, mirror plan, and sin exp N alpha pitch angle proton angular distributions are used to compute the instrument proton flux and dose count response functions and geometric factors for power law and Maxwellian proton energy spectra. Comparisons of the geometric factor computations using the path length method with the infinite slab approximation and the truncated infinite slab path length distribution are also made. Tables and graphs of modeled instrument performance are provided. Author (revised)

A dynamic simulator of the TOPAZ 2 reactor system has been developed for the Nuclear Electric Propulsion Space Test Program. The simulator combines first-principle modeling and empirical correlations in its algorithm to attain the modeling accuracy and computational through-put that are required for real-time execution. The overall execution time of the simulator for each time step is 15 ms when no data is written to the disk and 18 ms when nine double precision data points are written to the disk once in every time step. The simulation program has been tested, and it is able to handle a step decrease of 8 dollars worth of reactivity. It also provides simulations of fuel, emitter, collector, stainless steel, and ZrH moderator failures. Presented in this paper are the models used in the calculations, a sample simulation session, and a discussion of the performance and limitations of the simulator. The simulator has been found to provide realistic real-time dynamic response of the TOPAZ 2 reactor system under both normal and casualty conditions. DOE

A REVIEW OF CARBIDE FUEL CORROSION FOR NUCLEAR THERMAL PROPULSION APPLICATIONS
Dennis G. Pelaccio (New Mexico Univ., Albuquerque.), Mohamed S. El-Genk (New Mexico Univ., Albuquerque.), and Darryl P. Butt 1993 14 p Presented at the 11th Symposium on Space Nuclear Power Systems, Albuquerque, NM, 9-13 Jan. 1994
(Contract W-7405-eng-36)
(DE94-003938; LA-UR-93-4136; CONF-940101-26) Avail: CASI HC A03/MF A01

At the operation conditions of interest in nuclear thermal propulsion reactors, carbide materials have been known to exhibit a number of life limiting phenomena. These include the formation of liquid, loss by vaporization, creep and corresponding gas flow restrictions, and local corrosion and fuel structure degradation due to excessive mechanical and/or thermal loading. In addition, the radiation environment in the reactor core can produce a substantial change in its local physical properties, which can produce high thermal stresses and corresponding stress fractures (cracking). Time-temperature history and cyclic operation of the nuclear reactor can also accelerate some of these processes. The University of New Mexico's Institute for Space Nuclear Power Studies, under NASA sponsorship has recently initiated a study to model the complicated hydrogen corrosion process. In support of this effort, an extensive review of the open literature was performed, and a technical expert workshop was conducted. This paper summarizes the results of this review. DOE

ABLATION OF SOLID-PROPELLANT ROCKET-MOTOR NOZZLE MATERIALS
V. Borie (Office National d'Etudes et de Recherches Aerospatiales, Paris, France.) May 1993 306 p Transl. into ENGLISH of Ablation des Materiaux de Tuyeres de Propulseurs a Propergol Solide (Paris, France, ONERA) 1990 p 1-247 Original language document announced as N92-28780
(ESA-TT-1289; ONERA-NT-1990-13; ETN-94-95197) Avail: CASI HC A14/MF A03

An aerothermochemical analysis of the ablation of carbon-carbon materials located at the nozzle throats of large rocket motors was developed. This analysis includes the calculation of the equilibrium characteristics of the combustion products in the chamber, the calculation of the characteristics in the inviscid part of the flow in the nozzle, the determination of the convective transfer coefficients along the walls of the nozzle, the acquisition of experimental data concerning the ablation rates and the surface roughness of the carbon-carbon materials constituting the nozzle throats, a description of the chemical attack of these materials by the aggressive species present in the combustion products of the solid propellants, and the computer evaluation of the heat transfer and of the ablation of large rocket motor nozzle throats. The experimental results obtained are compared with the experimental data of the same type provided in the literature concerning the ablation of carbon materials. The computed results are in good agreement with the measured ablations on large scale rocket motors when the hypothesis of a transition between a laminar boundary layer flow existing on a virgin material and a turbulent boundary layer flow existing on very rough material during ablation is made in the modeling. SMALL LOW MASS ADVANCED PBR'S FOR BI-MODAL OPERATION
H. Ludewig, M. Todosow, and J. R. Powell 1 Oct. 1993 6 p Presented at the 11th Symposium on Space Nuclear Power Systems, Albuquerque, NM, 9-13 Jan. 1994
(Contract DE-AC02-76CH-00016)
(DE94-003201; BNL-49663; CONF-940101-23) Avail: CASI HC A02/MF A01

A preliminary assessment is made of a low mass bimodal reactor for use as a propulsion unit and as a heat source for generating electricity. This reactor is based on the particle bed reactor (PBR) concept. It will be able to generate both thrust and electricity simultaneously. This assessment indicates that the reactor can generate approximately 6.8 (4) N of thrust using hydrogen as a coolant and 100 KWe using a closed Brayton cycle (CBC) power conversion system. Two cooling paths pass through the reactor allowing a simultaneous operation of both modes. The development of all the components for this reactor are within the experience base of the NTP project. SPACE-R THERMIONIC SPACE NUCLEAR POWER SYSTEM: DESIGN AND TECHNOLOGY DEMONSTRATION
Oct. 1993 13 p

(Contract DE-AC03-92SF-19441)
(DE94-001890; DOE/SF-19441/T5) Avail: CASI HC A03/MF A01 (US Sales Only)

The preferred moderator being considered for SPACE-R is yttrium hydride encased in beryllium tubes. The baseline beryllium performs a dual function as it acts as a moderator and provides containment for hydrogen. The permeation rate of hydrogen from the hydride through the beryllium shell at the operating temperature is an important factor for the functionality and reliability of the Be-YHx moderator. Hydrogen containment capability of beryllium is comparable to enamel which was used in SNAP and Topaz 2 reactors. However, limited experimental data base exists for the hydrogen permeation through fabricated beryllium enclosures at high temperature. Permeation of hydrogen in beryllium is strongly affected by surface conditions, thickness of surface oxide, surface and bulk traps, impurity content, and microstructure. The objective of this experiment is to determine the permeation rate of hydrogen from yttrium hydride and zirconium hydride through beryllium in the temperature range of 773 to 973 K. In addition, Topaz 2 type zirconium hydride specimens with and without the proprietary oxide coating canned in stainless steel will be tested to measure the hydrogen permeation rate. The thermionic system evaluation test (TSET) stainless steel canned ZrHx samples currently at Phillips Laboratory will be used for the latter test with Phillips Laboratory participation at the Space Power, Incorporated, hydrogen leak test stand. A key technology demonstration of the effectiveness of transferred arc plasma spraying of a 1 mil molybdenum coating on the Be cladding will be performed. The effectiveness of the molybdenum coating in preventing any interaction of Be with stainless steel in NaK will be assessed and demonstrated. DOE

RISK PERSPECTIVES FOR TOPAZ 2 FLIGHT MISSION
A. C. Payne, Jr. and F. E. Haskin (New Mexico Univ., Albuquerque.) 1993 6 p Presented at the 11th Symposium on Space Nuclear Power Systems, Albuquerque, NM, 9-13 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-003229; SAND-93-2297C; CONF-940101-20) Avail: CASI HC A02/MF A01

The purpose of this paper is to present a preliminary estimate of the nuclear-related public health risk presented by launching and operating the Russian Topaz 2 space reactor as part of the Nuclear Electric Propulsion Space Test Program (NEPSTP). This risk is then compared to the risks from the operation of commercial nuclear power reactors and previously planned and/or launched space nuclear power missions. For the current mission profile, the initial estimate of the risk posed by launching and operating Topaz 2 is significantly less (at least two orders of magnitude) than that estimated for prior space nuclear missions. Even allowing for the large uncertainties in this estimate, it does not appear that the NEPSTP mission will present a significant health risk to the public. DOE

NUCLEAR ELECTRIC PROPULSION FOR FUTURE NASA SPACE SCIENCE MISSIONS
Chen-wan L. Yen 20 Jul. 1993 65 p
(Contract DE-AI03-91SF-19043)
(DE93-019086; DOE/SF-19043/T4; JPL-PUB-D-10689) Avail: CASI HC A04/MF A01

This study was made to assess the needs, potential benefits and the applicability of early (circa year 2000) Nuclear Electric Propulsion (NEP) technology in conducting NASA science missions. The study goals are: to obtain the performance characteristics of near term NEP technologies; to measure the performance potential of NEP for important OSSA missions; to compare NEP performance with that of conventional chemical propulsion; to identify key NEP system requirements; to clarify and depict the degree of importance NEP might have in advancing NASA space science goals; and to disseminate the results in a format useful to both NEP users and technology developers. This is a mission performance study and precludes investigations of multitudes of new mission operation and systems design issues attendant in a NEP flight. DOE

AN INVESTIGATION OF MAGNETIC FIELD EFFECTS ON PLUME DENSITY AND TEMPERATURE PROFILES OF AN APPLIED-FIELD MPD THRUSTER
S. Ray Bullock and R. M. Myers (Sverdrup Technology, Inc., Brook Park, OH.) Jan. 1994 14 p Presented at the 23rd International Electric Propulsion Conference, Seattle, WA, 13-16 Sep. 1993; sponsored by AIAA
(Contract NAS3-25266; RTOP 506-42-31)
(NASA-TM-106416; E-8253; NAS 1.15:106416; IEPC-93-140) Avail: CASI HC A03/MF A01

Applied-field magnetoplasmadynamic (MPD) thruster performance is below levels required for primary propulsion missions. While MPD thruster performance has been found to increase with the magnitude of the applied-field strength, there is currently little understanding of the impact of applied-field shape on thruster performance. The results of a study in which a single applied-field thruster was operated using three solenoidal magnets with diameters of 12.7, 15.2, and 30.4-cm are presented. Thruster voltage and anode power deposition were measured for each applied field shape over a range of field strengths. Plume electron number density and temperature distributions were measured using a Langmuir probe in an effort to determine the effect of field shape on plume confinement by the diverging magnetic-field for each of the three magnetic field shapes. Results show that the dependence of the measured thruster characteristics on field shape were non-monotonic and that the field shape had a significant effect on the plume density and temperature profiles. ORBIT TRANSFER ROCKET ENGINE TECHNOLOGY PROGRAM ENHANCED HEAT TRANSFER COMBUSTOR TECHNOLOGY Final Report, Jan. 1986 - Dec. 1991
William S. Brown Dec. 1991 143 p
(Contract NAS3-23773)
(NASA-CR-189236; NAS 1.26:189236; RI/RD91-235) Avail: CASI HC A07/MF A02

In order to increase the performance of a high performance, advanced expander-cycle engine combustor, higher chamber pressures are required. In order to increase chamber pressure, more heat energy is required to be transferred to the combustor coolant circuit fluid which drives the turbomachinery. This requirement was fulfilled by increasing the area exposed to the hot-gas by using combustor ribs. A previous technology task conducted 2-d hot air and cold flow tests to determine an optimum rib height and configuration. In task C.5 a combustor calorimeter was fabricated with the optimum rib configuration, 0.040 in. high ribs, in order to determine their enhancing capability. A secondary objective was to determine the effects of mixture ratio changers on the enhancement during hot-fire testing. The program used the Rocketdyne Integrated Component Evaluator (ICE) reconfigured into a thrust chamber only mode. The test results were extrapolated to give a projected enhancement from the ribs for a 16 in. long cylindrical combustor at 15 Klb nominal thrust level. The hot-gas wall ribs resulted in a 58 percent increase in heat transfer. When projected to a full size 15K combustor, it becomes a 46 percent increase. The results of those tests, a comparison with previous 2-d results, the effects of mixture ratio and combustion gas flow on the ribs and the potential ramifications for expander cycle combustors are detailed. GASEOUS HYDROGEN/OXYGEN INJECTOR PERFORMANCE CHARACTERIZATION Final Report
W. A. deGroot and H. H. Tsuei (Pennsylvania State Univ., University Park.) Feb. 1994 11 p Presented at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(Contract NAS3-25266; RTOP 506-42-31)
(NASA-CR-194464; E-8513; NAS 1.26:194464; AIAA Paper 94-0220) Avail: CASI HC A03/MF A01

Results are presented of spontaneous Raman scattering measurements in the combustion chamber of a 110 N thrust class gaseous hydrogen/oxygen rocket. Temperature, oxygen number density, and water number density profiles at the injector exit plane are presented. These measurements are used as input profiles to a full Navier-Stokes computational fluid dynamics (CFD) code. Predictions of this code while using the measured profiles are compared with predictions while using assumed uniform injector profiles. Axial and radial velocity profiles derived from both sets of predictions are compared with Rayleigh scattering measurements in the exit plane of a 33:1 area ratio nozzle. Temperature and number density Raman scattering measurements at the exit plane of a test rocket with a 1:1.36 area ratio nozzle are also compared with results from both sets of predictions.

STATIONARY PLASMA THRUSTER PLUME EMISSIONS Final Report
David H. Manzella Mar. 1994 13 p Presented at the 23rd International Electric Propulsion Conference, Seattle, WA, 13-16 Sep. 1993; sponsored by AIAA
(Contract NAS3-25266; RTOP 506-42-31)
(NASA-CR-194471; E-8612; NAS 1.26:194471; IEPC-93-097) Avail: CASI HC A03/MF A01

The emission spectrum from a xenon plasma produced by a Stationary Plasma Thruster provided by the Ballistic Missile Defense Organization (BMDO) was measured. Approximately 270 individual Xe I, Xe II, and XE III transitions were identified. A total of 250 mW of radiated optical emission was estimated from measurements taken at the thruster exit plane. There was no evidence of erosion products in the emission signature. Ingestion and ionization of background gas at elevated background pressure was detected. The distribution of excited states could be described by temperatures ranging from fractions of 1 eV to 4 eV with a high degree of uncertainty due to the nonequilibrium nature of this plasma. The plasma was over 95 percent ionized at the thruster exit plane. Between 10 and 20 percent of the ions were doubly charged. Two modes of operation were identified. The intensity of plasma emission increased by a factor of two during operation in an oscillatory mode. The transfer between the two modes of operation was likely related to unidentified phenomena occurring on a time scale of minutes. Author (revised)

STS-51 PAD ABORT. OV103-ENGINE 2033 (ME-2) FUEL FLOWMETER SENSOR OPEN CIRCUIT
12 Aug. 1993 168 p
(Contract NAS8-40000)
(NASA-CR-193924; NAS 1.26:193924; RSS-8912) Avail: CASI HC A08/MF A02

The STS-51 initial launch attempt of Discovery (OV-103) was terminated on KSC launch pad 39B on 12 Aug. 1993 at 9:12 AM E.S.T. due to a sensor redundancy failure in the liquid hydrogen system of ME-2 (Engine 2033). The event description and time line are summarized. Propellant loading was initiated on 12 Aug. 1993 at 12:00 AM EST. All space shuttle main engine (SSME) chill parameters and Launch Commit Criteria (LCC) were nominal. At engine start plus 1.34 seconds a Failure Identification (FID) was posted against Engine 2033 for exceeding the 1800 spin intra-channel (A1-A2) Fuel Flowrate sensor channel qualification limit. The engine was shut down at 1.50 seconds followed by Engines 2032 and 2030. All shut down sequences were nominal and the mission was safely aborted. SSME Avionics hardware and software performed nominally during the incident. A review of vehicle data table (VDT) data and controller software logic revealed no failure indications other than the single FID 111-101, Fuel Flowrate Intra-Channel Test Channel A disqualification. Software logic was executed according to requirements and there was no anomalous controller software operation. Immediately following the abort, a Rocketdyne/NASA failure investigation team was assembled. The team successfully isolated the failure cause to an open circuit in a Fuel Flowrate Sensor. This type of failure has occurred eight previous times in ground testing. The sensor had performed acceptably on three previous flights of the engine and SSME flight history shows 684 combined fuel flow rate sensor channel flights without failure. The disqualification of an Engine 2 (SSME No. 2033) Fuel Flowrate sensor channel was a result of an instrumentation failure and not engine performance. All other engine operations were nominal. This disqualification resulted in an engine shutdown and safe sequential shutdown of all three engines prior to ignition of the solid boosters. Author (revised)

TEST RESULTS OF THE RS-44 INTEGRATED COMPONENT EVALUATOR LIQUID OXYGEN/HYDROGEN ROCKET ENGINE Final Report, Apr. 1986 - Apr. 1987
R. F. Sutton and B. W. Lariviere 12 Oct. 1993 381 p
(Contract NAS3-23773)
(NASA-CR-194443; NAS 1.26:194443; RI/RD92-127) Avail: CASI HC A17/MF A03

An advanced LOX/LH2 expander cycle rocket engine, producing 15,000 lbf thrust for Orbital Transfer Vehicle missions, was tested to determine ignition, transition, and main stage characteristics. Detail design and fabrication of the pump fed RS44 integrated component evaluator (ICE) was accomplished using company discretionary resources and was tested under this contracted effort. Successful demonstrations were completed to about the 50 percent fuel turbopump power level (87,000 RPM), but during this last test, a high pressure fuel turbopump (HPFTP) bearing failed curtailing the test program. No other hardware were affected by the HPFTP premature shutdown. The ICE operations matched well with the predicted start transient simulations. The tests demonstrated the feasibility of a high performance advanced expander cycle engine. All engine components operated nominally, except for the HPFTP, during the engine hot-fire tests. A failure investigation was completed using company discretionary resources. Author

(AD-A274973; PL-TR-93-3053) Avail: CASI HC A04/MF A01

Recent studies show the Dense Plasma Focus (DPF) to be a viable candidate for use as a long-range space propulsion system with a high power-to-weight ratio. This Air Force contract provided support for study and modification of the University of Illinois (UI) DPF to develop a basic thrust experiment. A key aspect of such a system is to employ gas injection into the DPF electrode region, as opposed to the static fill technique commonly employed in present experimental devices. The design and initial operation of a prototype gas-puff injection facility is described, preliminary results are reviewed, and plans for future use are detailed. The projected performance of a future propulsion system using this technique is also examined. A list of the publications and conference presentations based on research done under this contract is included. DTIC

ORBIT TRANSFER ROCKET ENGINE TECHNOLOGY PROGRAM Final Report, Jun. 1983 - May 1992

N. B. Gustafson and T. J. Harmon 15 Oct. 1993 127 p
(Contract NAS3-23773)
(NASA-CR-189229; NAS 1.26:189229; RI/RD92-139) Avail: CASI HC A07/MF A02

An advanced near term (1990's) space-based Orbit Transfer Vehicle Engine (OTVE) system was designed, and the technologies applicable to its construction, maintenance, and operations were developed under Tasks A through F of the Orbit Transfer Rocket Engine Technology Program. Task A was a reporting task. In Task B, promising OTV turbomachinery technologies were explored: two stage partial admission turbines, high velocity ratio diffusing crossovers, soft wear ring seals, advanced bearing concepts, and a rotordynamic analysis. In Task C, a ribbed combustor design was developed. Possible rib and channel geometries were chosen analytically. Rib candidates were hot air tested and laser velocimeter boundary layer analyses were conducted. A channel geometry was also chosen on the basis of laser velocimeter data. To verify the predicted heat enhancement effects, a ribbed calorimeter spool was hot fire tested. Under Task D, the optimum expander cycle engine thrust, performance and envelope were established for a set of OTV missions. Optimal nozzle contours and quick disconnects for modularity were developed. Failure Modes and Effects Analyses, maintenance and reliability studies and component study results were incorporated into the engine system. Parametric trades on engine thrust, mixture ratio, and area ratio were also generated. A control system and the health monitoring and maintenance operations necessary for a space-based engine were outlined in Task E. In addition, combustor wall thickness measuring devices and a fiberoptic shaft monitor were developed. These monitoring devices were incorporated into preflight engine readiness checkout procedures. In Task F, the Integrated Component Evaluator (I.C.E.) was used to demonstrate performance and operational characteristics of an advanced expander cycle engine system and its component technologies. Sub-system checkouts and a system blowdown were performed. Short transitions were then made into main combustor ignition and main stage operation. Author (revised)

AN ASSESSMENT OF TESTING REQUIREMENT IMPACTS ON NUCLEAR THERMAL PROPULSION GROUND TEST FACILITY DESIGN

L. R. Shipers, C. A. Ottinger, and L. C. Sanchez 25 Oct. 1993 13 p Presented at the 11th Symposium on Space Nuclear Power Systems, Albuquerque, NM, 9-13 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-002933; SAND-93-2296C; CONF-940101-18) Avail: CASI HC A03/MF A01

Programs to develop solid core nuclear thermal propulsion (NTP) systems were under way at the Department of Defense (DoD), the National Aeronautics and Space Administration (NASA), and the Department of Energy (DOE). These programs recognized the need for a new ground test facility to support development of NTP systems. However, the different military and civilian applications have led to different ground test facility requirements. The Department of Energy (DOE) in its role as landlord and operator of the proposed research reactor test facilities initiated an effort to explore opportunities for a common ground test facility to meet both DoD and NASA needs. The baseline design and operating limits of the proposed DoD NTP ground test facility are described. The NASA ground test facility requirements are reviewed and their potential impact on the DoD facility baseline is discussed. DOE

HANDBOOK FOR HANDLING AND STORAGE OF NICKEL-CADMIUM BATTERIES: LESSONS LEARNED

Floyd E. Ford (Swales and Associates, Beltsville, MD.), Gopalakrishna M. Rao, and Thomas Y. Yi Feb. 1994 77 p
(Contract NAS5-30375)
(NASA-RP-1326; NAS 1.61:1326; Rept-94B00027) Avail: CASI HC A05/MF A01

The handbook provides guidelines for the handling and storage of conventional NiCd flight batteries. The guidelines are based on many years of experience with ground and in-flight handling of batteries. The overall goal is to minimize the deterioration and irreversible effects of improper handling of NiCd flight batteries on flight performance. A secondary goal is to provide the reader with an understanding, in nonanalytical terms, of the degradation mechanisms of NiCd cells and how these mechanisms are affected by improper ground handling of flight hardware. Section 2 provides the reader with a brief introduction to NiCd cells. The effects of the environment on NiCd batteries are discussed in Section 3, and Section 4 contains 12 guidelines for battery handling and storage with supporting rationale for each guideline. The appendix provides a synopsis of NiCd cell design and evolution over 30 years of space flight on Goddard Space Flight Center (GSFC) satellites, along with a chronological review of key events that influenced the design of NiCd cells being flown today. VERIFICATION OF THERMAL ANALYSIS CODES FOR MODELING SOLID ROCKET NOZZLES Final Report

M. Keyhani (Tennessee Univ., Knoxville.) May 1993 22 p
(Grant NAG8-212)
(NASA-CR-195248; NAS 1.26:195248; UTK-R01-1372-59) Avail: CASI HC A03/MF A01

One of the objectives of the Solid Propulsion Integrity Program (SPIP) at Marshall Space Flight Center (MSFC) is development of thermal analysis codes capable of accurately predicting the temperature field, pore pressure field and the surface recession experienced by decomposing polymers which are used as thermal barriers in solid rocket nozzles. The objective of this study is to provide means for verifications of thermal analysis codes developed for modeling of flow and heat transfer in solid rocket nozzles. In order to meet the stated objective, a test facility was designed and constructed for measurement of the transient temperature field in a sample composite subjected to a constant heat flux boundary condition. The heating was provided via a steel thin-foil with a thickness of 0.025 mm. The designed electrical circuit can provide a heating rate of 1800 W. The heater was sandwiched between two identical samples, and thus ensure equal power distribution between them. The samples were fitted with Type K thermocouples, and the exact location of the thermocouples were determined via X-rays. The experiments were modeled via a one-dimensional code (UT1D) as a conduction and phase change heat transfer process. Since the pyrolysis gas flow was in the direction normal to the heat flow, the numerical model could not account for the convection cooling effect of the pyrolysis gas flow. Therefore, the predicted values in the decomposition zone are considered to be an upper estimate of the temperature. From the analysis of the experimental and the numerical results the following are concluded: (1) The virgin and char specific heat data for FM 5055 as reported by SoRI can not be used to obtain any reasonable agreement between the measured temperatures and the predictions. However, use of virgin and char specific heat data given in Acurex report produced good agreement for most of the measured temperatures. (2) Constant heat flux heating process can produce a much higher heating rate than the radiative heating process. The results show that heating rates of 125 C/s (225 F/s) can be achieved. (3) The electrical resistance of the FM 5055 samples were about 150 Omega in the virgin state, and decreased to about 35 Omega when charred. A reliable scheme must be developed to electrically insulate the composite from the heater foil in order to prevent any current leakage into the sample which can result in volumetric heating of the char zone of the composite.

ORBITAL TRANSFER VEHICLE ENGINE TECHNOLOGY HIGH VELOCITY RATIO DIFFUSING CROSSOVER Final Report, Dec. 1983 - 1989
Brian W. Lariviere Dec. 1992 155 p
(Contract NAS3-23773)
(NASA-CR-194447; NAS 1.26:194447; RI/RD89-111) Avail: CASI HC A08/MF A02

High speed, high efficiency head rise multistage pumps require continuous passage diffusing crossovers to effectively convey the pumped fluid from the exit of one impeller to the inlet of the next impeller. On Rocketdyne's Orbital Transfer Vehicle (OTV), the MK49-F, a three stage high pressure liquid hydrogen turbopump, utilizes a 6.23 velocity ratio diffusing crossover. This velocity ratio approaches the diffusion limits for stable and efficient flow over the operating conditions required by the OTV system. The design of the high velocity ratio diffusing crossover was based on advanced analytical techniques anchored by previous tests of stationary two-dimensional diffusers with steady flow. To secure the design and the analytical techniques, tests were required with the unsteady whirling characteristics produced by an impeller. A tester was designed and fabricated using a 2.85 times scale model of the MK49-F turbopumps first stage, including the inducer, impeller, and the diffusing crossover. Water and air tests were completed to evaluate the large scale turbulence, non-uniform velocity, and non-steady velocity on the pump and crossover head and efficiency. Suction performance tests from 80 percent to 124 percent of design flow were completed in water to assess these pump characteristics. Pump and diffuser performance from the water and air tests were compared with the actual MK49-F test data in liquid hydrogen. Author

A STUDY OF DC-DC CONVERTERS WITH MCT'S FOR ARCJET POWER SUPPLIES Final Report
Thomas A. Stuart Jan. 1994 76 p
(Grant NAG3-1102; RTOP 506-42-31)
(NASA-CR-191204; E-8386; NAS 1.26:191204) Avail: CASI HC A05/MF A01

Many arcjet DC power supplies use PWM full bridge converters with large arrays of parallel FET's. This report investigates an alternative supply using a variable frequency series resonant converter with small arrays of parallel MCT's (metal oxide semiconductor controlled thyristors). The reasons for this approach are to: increase reliability by reducing the number of switching devices; and decrease the surface mounting area of the switching arrays. The variable frequency series resonant approach is used because the relatively slow switching speed of the MCT precludes the use of PWM. The 10 kW converter operated satisfactorily with an efficiency of over 91 percent. Test results indicate this efficiency could be increased further by additional optimization of the series resonant inductor. Author

The optimized geometry of 1, C2H5-0-C(double bonds oxygen)N(NO2)2, a precursor to ammonium dinitramide, has been computed at the ab initio HF/6-31G* level. We find no structural evidence that 1 exists in the ionic form, C2H5-O-C(triple bonds)O + N(NO2)2(-). The reaction of 1 with NH3 passes through a transition state that is consistent with a concerted substitution (Ingold mechanism) in which N(NO2)2(-) is the leaving group. DTIC

Preparation, characterization, and reactivity of ((eta)(sup 2) alkyne)(meso tetratolylpoprphrinato) titanium(II) complexes are described, along with intermetal oxygen atom transfer reactions involving Ti(IV) and Ti(III) porphyrin complexes. The (eta)(sup 2)- alkyne complexes are prepared by reaction of (TTP)TiCl2 with LiAlH4 in presence of alkyne. Structure of (OEP)Ti((eta)(sup 2)-Ph-C(triple bond)C-Ph) (OEP=octaethylporphryin) was determined by XRD. The compounds undergo simple substitution to displace the alkyne and produce doubly substituted complexes. Structure of (TTP)Ti(4-picoline)(sub 2) was also determined by XRD. Reaction of (TTP)Ti(double bond)O with (OEP)Ti-Cl yields intermetal O/Cl exchange, which is a one-electron redox process mediated by O atom transfer. Also a zero-electron redox process mediated by atom transfer is observed when (TTP)TiCl2 is reacted with (OEP)Ti(double bond)O. DOE

Adding hindered amine light stabilizers (HALS) to N-methyl- pyrrolidinone (NMP) solutions of polyaniline delays gelation. It is hypothesized that HALS act in some manner other than as traditional antioxidants in preventing gelation; the secondary amine functional group appears to play a critical role, perhaps by disrupting the physical crystallization network that may contribute to gelation. Pyrrolidine, a secondary amine, or ammonia is an effective cosolvent with NMP in dissolving PAn-EB (emeraldine base). DOE

This program aims at improving current methods of lifetime assessment by building in the characteristics of the micro-mechanisms known to be responsible for damage and failure. The broad approach entails the integration, where necessary, augmentation of the micro-scale research results currently available in the literature into a macro-scale model with predictive capability. In more detail, the program will develop a set of hierarchically structured models at different length scales, from atomic to macroscopic, at each level taking as parametric input the results of the model at the next smaller scale. In this way the known microscopic properties can be transported by systematic procedures to the unknown macro-scale region. It may not be possible to eliminate empiricism completely, because some of the quantities involved cannot yet be estimated to the required degree of precision. In this case the aim will be at least to eliminate functional empiricism. DTIC

Continuous reinforced thermoplastic composites are addressed. Thermoplastic materials represent only a fraction of the total market for polymer matrix structural composites. However, there are numerous reasons for increased use of thermoplastic materials as load bearing structures. One of the foremost is that they are environmentally friendly due to their nonreactive solvent free processing and recycling. Thermoplastic matrix systems also have some technical advantages in service. For example, toughness, chemical resistance, and short production cycle times are some of the finest properties of thermoplastic composites. The main limitations on the use of continuous fiber reinforced thermoplastic composites are their molding properties. The high viscosity of polymer melts somewhat limits their production methods. Production is usually of quite simple parts, such as plates and continuous profiles. Furthermore, the required high molding pressures increase production costs in short series. One stage in the production of continuous fiber reinforced thermoplastic composites is the impregration process. A number of different methods and variations of them have been developed. Focus is given to the hybrid yarn method. Another essential fact is the factor controlling the moldability of these kinds of materials. Different viscosity properties of polymer melts, including very long or continuous fibers, are described. ESA

EFFECT OF IMPACT FACE DAMAGE ON STRENGTH OF SANDWICH COMPOSITES

Pertti Auerkari Jan. 1993 23 p
(ISSN 1235-0621)
(VTT-PUBS-128; ISBN-951-38-4246-0; ETN-94-95247) Copyright Avail: CASI HC A03/MF A01

The effect of accidental impacts during manufacturing, maintenance or servicing of marine and aerospace sandwich structures is discussed. In particular, the effect of low energy impact damage on residual strength is considered. Methods for evaluating the service performance of accidentally impact loaded sandwich structures are proposed. A low energy impact face defect decreases the face load of a sandwich composite. The expression describing the critical lateral face load in compression is discussed. Experimental studies suggest that the diameter of the impact delamination defect is approximately equal to the impact energy multiplied by the square root of the number of equal impacts, which corresponds to the critical energy criterion for fatigue. INVESTIGATION OF COMPRESSIVE BEHAVIOR FOR METAL MATRIX COMPOSITES WITH A CIRCULAR HOLE M.S. Thesis
Janet L. Gooder Dec. 1993 135 p
(AD-A273835; AFIT/GAE/ENY/93D-15) Avail: CASI HC A07/MF A02

The notched and unnotched macromechanical response due to micromechanical behavior of (O/+ or -45/90)(sub s) SCS-6/Beta 21S and (0/90)(sub 2S), Sigma/Beta 21S subjected to static compressive loads at room temperature was investigated. The stress-strain behavior and mechanical response in the presence of a circular hole was examined. A clear description of the progressive nature of damage, which ultimately resulted in failure, was provided. The effect of elevated temperature was shown for SCS-6/Beta 21S. The ultimate compressive strength and elastic modulus were reported for both MMC's. Sigma/Beta 21S and SCS-6/Beta 21S were mildly notch sensitive at room temperature. Notch sensitivity of SCS-6/Beta 21S was slightly reduced at 650 C. Internal failure mechanisms of fiber debonding, matrix cracking, matrix yielding, fiber failure, and fiber microbuckling were observed in various combinations during the loading. Damage mechanisms were observed similarly in notched and unnotched specimens. Damage initiation in the notched specimens was concentrated in the region adjacent to the hole. Sigma/Beta 21S and unnotched SCS-6/Beta 21S at room temperature failed in an extensional mode, while notched SCS-6/Beta 21S and unnotched SCS-6/Beta 21S at 650 C failed in a shear mode. The ultimate compressive failure of each depended on the ultimate strength of the fibers. DTIC

X RAY COMPUTED TOMOGRAPHY FOR EMERGING AEROSPACE MATERIALS AND PROCESSES DEVELOPMENT Interim Report, Sep. 1991 - May 1993
Richard H. Bossi, Gary E. Georgeson, and Raymond D. Rempt 1 May 1993 68 p
(Contract F33615-88-C-5404)
(AD-A273721; WL-TR-93-4054) Avail: CASI HC A04/MF A01

The development and qualification of new materials and processes requires characterization of the product as a function of manufacturing and operational parameters. X ray computed tomography (CT) provides quantitative measurements of material characteristics in terms of the dimensions, density, and composition. The results of studies involving CT testing of various materials demonstrate the ability of CT to provide valuable information for material process understanding and characterization. The cost benefit of CT is found in the reduction of risk and schedule savings by reducing cycle time in process development steps. CT is a tool which increases new design options by allowing internal measurement and evaluation at previously inaccessible locations in complex structures. X ray CT will be a critical tool for organizations competing in emerging materials and processes development. DTIC

STRUCTURE AND PROPERTIES OF INTERMETALLIC COMPOSITES SYNTHESIZED IN SITU USING SOLID STATE DISPLACEMENT REACTIONS
C. H. Henager, Jr., J. L. Brimhall, and J. P. Hirth (Washington State Univ., Pullman.) Sep. 1993 29 p Presented at the 1st International Symposium on Structural Intermetallics, Champion, PA, 26-30 Sep. 1993
(Contract DE-AC06-76RL-01830)
(DE94-004312; PNL-SA-22561; CONF-930997-7) Avail: CASI HC A03/MF A01

Solid state displacement reactions can produce in situ intermetallic matrix composites in a process where an intermetallic phase(s) and a potential reinforcing phase(s) are grown together during a solid state reaction. Interwoven and dispersed microstructures, important for desirable composite properties, have been produced by means of displacement reaction processing techniques. Two such composites have been synthesized: MoSi2 reinforced with SiC particles, and NiAl/Ni3Al reinforced with Al2O3. Strength in bending and chevron-notch fracture toughness have been determined as a function of temperature and measured properties compare favorably with composites produced by other means. The measured properties are discussed with regard to the observed microstructures. The potential for displacement reaction processing is assessed and appears to be a cost-effective synthesis method compared to others. DOE

A NONLINEAR THREE-DIMENSIONAL MICROMECHANICS MODEL FOR FIBER-REINFORCED LAMINATED COMPOSITES Ph.D. Thesis
David D. Robertson Nov. 1993 256 p
(AD-A273772; AFIT/DS/AA/93-3) Avail: CASI HC A12/MF A03

In this study, a three dimensional micromechanics model is developed. The present capabilities of the model include both unidirectional and laminated composite layups with various types of nonlinear analysis such as a thermoelastic-plastic analysis employing the Prandtl-Reuss flow relations, a thermoviscoplastic analysis using Bodner-Partom unified constitutive theory, and an interfacial damage progression scheme based on a statistical interfacial failure criteria. Such nonlinearities are critical factors during thermomechanical fatigue (TMF) loading of high temperature composites. Solutions were obtained and extensive comparisons performed with existing micromechanics models, finite element analysis, and experiment with excellent results. In addition, the analysis was developed to require minimal computer resources. For instance, the majority of problems may be accomplished on a personal computer in a matter of seconds. DTIC

INFLUENCE OF EMBEDDED OPTICAL FIBERS ON COMPRESSIVE STRENGTH OF ADVANCED COMPOSITES M.S. Thesis
Stefan B. Dosedel Dec. 1993 131 p
(AD-A273775; AFIT/GAE/ENY/93D-12) Avail: CASI HC A07/MF A02

This study investigated the effects of embedding optical fibers into advanced composite materials. This combination was meant to simulate 'smart structures' that have been shown to sense several different variables in the composite including strain, temperature, and damage. A laminate orientation taken from an existing aircraft structure was used to fabricate sixteen groups of specimens which were subjected to compression testing in an IITRI fixture to determine the ultimate compressive strength and modulus of elasticity. Ten of these groups were fabricated with optical fibers while the other six were control groups and contained no optical fibers. This study showed that varying the number of embedded optical fibers, optical fiber size, optical fiber orientation, and optical fiber location in the composite structure can reduce the compressive strength of the structure by up to 27%. This maximum degradation occurred when multiple optical fibers were placed perpendicular to the composite structural fibers. No deleterious effects were seen when the optical fiber was placed parallel to the composite structural fibers. No change in modulus of elasticity was seen for any of the groups tested. DTIC

A STUDY OF GRAPHITE PEEK COMPOSITE WITH CENTRAL ELLIPTICAL HOLES UNDER TENSION M.S. Thesis
Bill J. Lau Dec. 1993 123 p
(AD-A273779; AFIT/GAE/ENY/93D-20) Avail: CASI HC A06/MF A02

This study investigated the stress-strain response and failure modes of graphite / polyether etherketone (Gr/PEEK) tension specimens containing a central elliptical hole. Both experiments and finite element numerical analyses were conducted. Test specimens included seven layups and three hole geometries; three of each combination were tested. The holes consisted of an ellipse with major axis aligned with the load axis, an ellipse with major axis transverse to the load axis, and a circle. Strain gages were located adjacent to the hole and midway between the hole and tab on all specimens. Strain data was used to plot stress-strain response. The analysis utilized a nonlinear finite element program, assuming plane stress. Linear stress-strain relationships are applied incrementally; piecewise cubic spline interpolation functions represent the material data provided to the program, accounting for the material nonlinearity. A strain energy failure criterion determines element failures. Analytical stress-strain results correlated well with experiment, with some divergence noted. Damage progression of the finite element models agreed with observed failure surfaces, except for unidirectional and crossply layups. These failed more suddenly, and the program is unable to capture this phenomenon. Interlaminar stresses developing in the actual tests and coarse regions of the finite element meshes were identified as probable sources of error. DTIC

CHARACTERIZATION OF FATIGUE DAMAGE IN A METAL MATRIX COMPOSITE (SCS-6/Ti-15-3) AT ELEVATED TEMPERATURE Ph.D. Thesis

Brian P. Sanders Dec. 1993 324 p
(AD-A273797; AFIT/DS/AA/93-4) Avail: CASI HC A14/MF A03

The fatigue characteristics of a unidirectional titanium based metal matrix composite site (MMC) were investigated at elevated temperature (427 C). A hybrid strain controlled loading made was used to subject the 0 deg and 90 deg laminas to fatigue. Along with the fatigue tests, microscopy and analytical modeling were also conducted. This combination of activities led to defining the initiation and progression of damage and deformation in the MMC. When loading was parallel to the fiber direction, the fatigue behavior was initially dominated by creep deformation of the matrix. Then, depending on the maximum strain, specimen failure was the result either fiber fractures or matrix cracking. In contrast, when loading was perpendicular to the fiber direction, the fatigue response was first dominated by the initiation of fiber-matrix interface damage. Then, if the maximum strain was above .35%, the dominant damage mechanism was matrix cracking. Below this strain level, the damage was a mixture of matrix microcracks and the progression of fiber-matrix interface damage. The analysis for this fiber orientation included unique methods to model the interface damage. This hybrid approach involving experiments, microscopy, and analytical modeling provided better understanding of the fatigue behavior of the MCC. DTIC

NUMERICAL SIMULATIONS OF INTERFACIAL DEBONDING IN DUCTILE-PHASE REINFORCED INTERMETALLIC MATRIX COMPOSITES

G. A. Henshall, E. Zywicz, and M. J. Strum 10 Aug. 1993 18 p
Presented at the Mechanism and Mechanics of Composite Fracture Meeting, Pittsburgh, PA, 17-21 Oct. 1993
(Contract W-7405-eng-48)
(DE94-003639; UCRL-JC-114725; CONF-931078-2) Avail: CASI HC A03/MF A01

The fracture toughness of brittle intermetallic compounds can be improved by ductile-phase reinforcements. The effectiveness of the ductile phase in bridging cracks, and therefore increasing the composite toughness, is known qualitatively to depend upon the extent of debonding between the two phases. Numerical crack-growth simulations are used here to provide semi-quantitative predictions of the influence of interfacial debonding on the macroscopic stress-displacement behavior and, hence, the fracture toughness of an idealized Pb/glass composite. The interfacial toughness required to cause debonding, characterized by a constant critical energy release rate, is varied parametrically. As expected, higher interfacial toughness results in less interphase debonding, higher composite strength, and greater ductile-phase constraint. Consequently, the increase in ductile-phase triaxiality can potentially accelerate internal void formation and growth or facilitate cleavage fracture, either of which would likely decrease the toughness of the composite. GENERAL MOTORS CORPORATION AND PACIFIC NORTHWEST LABORATORY STAFF EXCHANGE: INSPECTION OF CASE HARDENED STEELS AND METAL-MATRIX COMPOSITES

M. S. Good and D. D. Rogers (General Motors Corp., Saginaw, MI.) Oct. 1993 19 p
(Contract DE-AC06-76RL-01830)
(DE94-003470; PNL-8926) Avail: CASI HC A03/MF A01

Staff exchanges, such as the one described in this report, are intended to facilitate communication and collaboration among scientists and engineers at Department of Energy (DOE) laboratories, in US industry, and academia. Funding support for these exchanges is provided by the DOE, Office of Energy Research, Laboratory Technology Transfer Program. The exchanges offer the opportunity for the laboratories to transfer technology and expertise to industry, gain a perspective on industry's problems, and develop the basis for further cooperative efforts through Cooperative Research and Development Agreements (CRADA's) or other mechanisms. The objectives of this report were as follows: for Pacific Northwest Laboratory (PNL) staff to present technology to General Motors (GM) staff on nondestructive measurement of hardened steel components and uniformity of particle dispersion in metal-matrix composites for evaluation for possible application in GM's manufacturing processes; for GM staff to discuss with PNL staff common manufacturing processes, metallurgy, and flaw criteria for hardening of various components and manufacturing of metal-matrix composites; and to provide an initial step in building a long-term collaborative relationship between PNL and GM. Information in this report on the staff exchange of PNL staff with GM Corporation includes the purpose and objectives, a summary of activities, significant accomplishments, significant problems, industry benefits realized, recommended follow-on work and potential benefits from that work, and three appendixes. Appendix A is a description of ultrasonic backscatter technology and its applications to the two nondestructive inspection interests defined by GM. Appendix B is a list of key contacts and the schedule of activities pertaining to the staff exchange. Appendix C is an article from American Society for Metals News relating to sensor needs. DOE

INVESTIGATION OF TENSION-COMPRESSION FATIGUE BEHAVIOR OF A CROSS-PLY METAL MATRIX COMPOSITE AT ROOM AND ELEVATED TEMPERATURES M.S. Thesis

Elizabeth A. Boyum Dec. 1993 165 p
(AD-A273731; AFIT/GAE/ENY/93D-6) Avail: CASI HC A08/MF A02

This research, the first load-controlled tension-compression fatigue testing to be performed on a MMC, extends the existing knowledge of MMC fatigue damage mechanisms to include the tension compression loading condition. To accomplish this, a (0/90) (sub 2s), SCS-6/Ti-15-3 laminate was subjected to tension-tension fatigue at room temperature, and tension-compression fatigue at both room temperature and 427 C. Stress and strain data was taken to evaluate the macro-mechanic behavior of the material. Microscopy and fractography were performed to characterize the damage on a micro-mechanic level. On a maximum applied stress basis, the room temperature tension-tension specimens had longer fatigue lives than the room temperature tension-compression specimens. The room and high temperature tension-compression fatigue lives were nearly identical in the fiber-dominated high stress region of the SN curve. However, the increased ductility and diffused plasticity of the titanium matrix at 427 C delayed the onset and severity of matrix cracking, and thus increased the elevated temperature fatigue lives in the matrix dominated region of the SN curve. In all cases, matrix damage initiated at reaction zone cracks which nucleated both matrix plasticity and matrix cracking. DTIC

FRACTURE BEHAVIOR OF 20% Nb PARTICULATE REINFORCED ALUMINA COMPOSITE

S. Lane, S. B. Biner, and O. Buck 1993 11 p Presented at the High Performance Metal and Ceramic Matrix Composites, San Francisco, CA, 27 Feb. - 3 Mar. 1994
(Contract W-7405-eng-82)
(DE94-002830; IS-M-775; CONF-940229-1) Avail: CASI HC A03/MF A01

The composites consist of alumina matrix with 0.05 wt % MgO and 20 Vol % Nb with an average particle size of 30 to 100 microns produced by dry mixing and sintering to near their theoretical densities. Fracture toughness tests were carried out in three point bending on chevron notched samples. Results indicate that R-curve of the composites exhibited more than 300%

increase in crack growth resistance compared to crack growth resistance of alumina produced with the identical procedures. Crack growth resistance curve of the composites increased with increasing Nb particle size. Metallorgraph indicated that failure of Nb particles in crack path ranges from full interface separation without any significant deformation of Nb particles to cleavage failure without any evidence of interface separation. DESIGN STUDY OF FIBER-COMPOSITE PENETRATOR CASES
R. W. Logan, S. E. Groves, and R. E. Lyon 22 Oct. 1993 15 p
Presented at the Annual Winter Meeting of the American Society of Mechanical Engineers, New Orleans, LA, 28 Nov. - 3 Dec. 1993
(Contract W-7405-eng-48)
(DE94-003203; UCRL-JC-114833; CONF-931121-33) Avail: CASI HC A03/MF A01

A design study was conducted to demonstrate the viability of carbon-fiber reinforced epoxy composites as structural case materials for penetrating warheads. The objective was to conduct well-instrumented experimental studies of composite-body penetrators perforating mild steel plates and quantitatively model these plate penetrations using two and three dimensional finite element codes over a wide range of velocities and impact conditions in order to develop predictive capability for composite design and for use in tradeoff studies with existing case materials. Understanding of the failure of composite-body penetrators would be demonstrated by a rational design iteration which significantly improved performance. Initial studies utilized existing one-degree tapered cylindrical carbon fiber/epoxy composite cases fabricated by wet-filament winding. These sharp-tipped, steel-nose, composite penetrators were strain-gaged, piggy-backed with 57 kilograms, and impacted into steel plates in a velocity-boosted droptower at impact velocities ranging from 3 to 18 meters per second. Load, time, and position data were recorded during the impact event as well as the axial and hoop strains in the composite case. Monolithic 4340 hardened steel penetrators with both sharp- and flat-tip three-caliber ogive noses were also impacted into mild steel plates. Data from the composite-case and steel penetrators were used to calibrate a multiaxial, rate-dependent, flow and failure model for the mild steel plates in NIKE2D. The authors were then able to successfully predict survival and failure of the composite-case penetrators in normal-incidence droptower tests for different target thickness and velocity combinations. THE EFFECTS OF EMBEDDED INTERNAL DELAMINATIONS ON COMPOSITE LAMINATE COMPRESSION STRENGTH; AN EXPERIMENTAL REVIEW
Alan T. Nettles Mar. 1994 23 p Sponsored by NASA, Washington
(NASA-TM-108440; NAS 1.15:108440) Avail: CASI HC A03/MF A01

Delaminations in laminated composite materials can degrade the compressive strength of these materials. Delaminations can form as a result of impact damage or processing flaws. In order to better understand the effects of these delaminations on the compressive behavior of laminated composite plates, programs have been conducted to assess the criticality of prescribed delaminations of known size, shape, and location on the compression strength of laminated composites. A review of these programs is presented along with highlights of pertinent findings from each. Author

EFFECTS OF POST-FABRICATION PROCESSING ON THE TENSILE PROPERTIES OF CENTRIFUGALLY CAST SiC PARTICULATE REINFORCED ALUMINUM COMPOSITES M.S. Thesis
Kurt A. Muller Sep. 1993 39 p
(AD-A274865) Avail: CASI HC A03/MF A01

A centrifugally cast A356 aluminum-matrix composite reinforced with silicon carbide (SiC) particles was thermomechanically processed by rolling and the resulting properties were studied. Tensile testing, hardness testing, and optical microscopy were conducted. This study included evaluations of the mechanical properties of the composite following rolling at varying strains, temperature, strain per pass, and aging treatments. The effects of both single and multistep rolling processes were evaluated, and the composites were tested following solution treatment. Testing revealed that the ductility was associated with progressive homogenization of the particulate distribution at increasing strain levels. It was found that rolling just under the solvus temperature produced poorer mechanical properties for the composite than for those rolled at a temperature significantly above or below the solvus temperature. Strain per pass was found to have insignificant effect on the final properties, with total strain being the controlling factor. For equal strength conditions, the underaged composite was more ductile than the overaged composite. DTIC

The following cases were studied experimentally: impact resistance and residual bending strength of a sandwich panel made of a PVC foam core between carbon fiber reinforced epoxy skins; fatigue life of a thick glass fiber reinforced epoxy laminate beam; and resistance to cyclic overheating and impact damage of glass fiber reinforced VE pressure vessels and pressure piping. The impact resistance of a sandwich composite with carbon fiber reinforced epoxy skin and PVC foam core was investigated by measuring the surface and intermediate layer damage after controlled and repeated impacts by a 20 mm spherical indenter. High resolution ultrasonic mapping was used for characterizing the internal delamination defects. The effect of non penetrating impacts on the residual bending strength was reasonably well predicted from both the incident impact energy and number of impacts as well as from the size of the ultrasonically determined impact damage. The bending strength of the laminate beams in cyclic loading was measured and the results were compared to the actual service conditions. The results show that the life time was mostly influenced by strongly localized damage at the point of peak stresses. Non insulated GFRP (Glass Fiber Reinforced Plastic) pipes were experimentally investigated, with particular consideration to the effects of short term thermal overloads and impact damage. It appears possible to significantly extend the service temperature range for this material in noninsulated pressure vessels and pipes, with consequent savings in optimizing material costs and process efficiency at the time of design. Impact testing and subsequent static pressure testing showed that for a given type of material, the leakage pressure of the vessel can be relatively easily predicted from the incident impact energy or from the ultrasonically determined size of the impact defect. (AD-A274693) Avail: CASI HC A01/MF A01

A two and a half year ONR/ARPA funded program to develop a low cost process for manufacture of a high strength/high modulus sigma/E boron nitride (BN) fiber was initiated on 7/1/90 and ended on 12/31/92. The preparation of high sigma/E BN fibers had been demonstrated in the late 1960's by the PI using a batch nitriding of B2O3 fiber with NH3 followed by stress graphitization at approximately 2000 deg C. Such fibers displayed values comparable to PAN based carbon fibers but the mechanicals were variable most likely because of redeposition of volatiles at 2000 deg C. In addition, the cost of the fibers was very high due to the need for many hours of nitriding necessary to convert the BsO3 fibers. the use of batch nitriding negated two possible cost advantages of this concept, namely, the ease of drawing very fine, multi-filament yarn of B2O3 and more importantly the very low cost of the starting materials. COMPOSITE RAW MATERIALS FOR THE BUILDING INDUSTRY [RAKENNUSTEOLLISUUDEN KOMPOSIITTIEN OSAMATERIAALIT]

Leena Sarvaranta, ed. Dec. 1992 93 p In FINNISH
(ISSN 1235-0605)
(VTT-TIED-1433; ISBN-951-38-4327-0; ETN-94-95260) Copyright Avail: CASI HC A05/MF A01

A composite material is obtained by combining two or more different components. Thus an interface exists between these components. Interfaces are often mechanically the weakest and chemically the most unstable spots within the composite material. The choice and use of building materials is related to their availability, price and reliability in design. However, designers do not always have the relevant data concerning new composite materials. In research and development of new composites, simple rules of thumb are needed for the preliminary design. For a heavier calculation and the analysis of test results, models are needed for evaluating the dimensioning value of a given quantity. Systems including fiber and matrix, particle and matrix, and laminate and core are discussed from a mechanistic point of view. A general outline is given of the fire properties of materials and some special properties of composites are discussed. Fire regulations and the applicability of calculation methods are discussed. An approach to the prediction of durability of building materials and products is presented. The influence of building materials on the environment is discussed with regard to mineral materials, metals, synthetic polymers and timber. Concrete, ceramic materials, metals, timber and polymers are reviewed as potential matrix materials for composites in the building industry. Carbon, ceramic, glass, metal, aramide, polyester, polyacrylonitrile, polyolefine and wood fibers are reviewed as potential reinforcement for different matrices. ESA

INVESTIGATION OF FORCED AND ISOTHERMAL CHEMICAL VAPOR INFILTRATED SiC/SiC CERAMIC MATRIX COMPOSITES

J. Sankar, A. D. Kelkar, and R. Vaidyanathan Sep. 1993 216 p
Prepared for Oak Ridge National Lab., TN
(Contract DE-AC05-84OR-21400)
(DE94-004544; ORNL/Sub-88-SC423/01) Avail: CASI HC A10/MF A03

Mechanical properties of two different layups for each of the forced chemical vapor infiltration (FCVI) (41 specimens) and isothermal chemical vapor infiltration (CVI) (36 specimens) materials were investigated in air at room temperature (RT), 1000 C, and at room temperature after thermal shock (RT/TS) and exposure to oxidation (RT/OX). The FCVI specimens had a nominal interfacial coating thickness of 0.3 microns of pyrolytic carbon, while CVI specimens had a coating thickness of 0.1 microns. Effect of reinforcement and interfacial bond on mechanical properties of composite were investigated. Scanning electron microscopy (SEM) and transmission electron microscopy (TEM) were employed to analyze the fiber-matrix interface and the toughening mechanisms in this ceramic composite system. DOE

FATIGUE RESISTANCE UNDER TENSION-COMPRESSION OF LAMINATES IM6/5245C AND AS4/3501-6 [RESISTANCE EN FATIGUE TENSION-COMPRESSION DES STRATIFIES IM6/5245C ET AS4/3501-6]

Dominique Lefebvre, Catherine Randon, Patrick Larose, and Clermont Roy Jun. 1993 164 p In FRENCH
(IAR-CR-25; NRC-32160; CTN-94-61008) Avail: CASI HC A08/MF A02

Results are presented from a study of two laminate layups (S2 and S12) made with the AS4/3501-6 graphite/epoxy system. The performance of these layups was observed under static and cyclic loading and compared with the performance obtained with IM6/5245C laminates. Quasi three dimensional finite element analysis was used to calculate the edge stresses. The tests were conducted with specimens 150 mm long and stabilized with anti-buckling guides for compression loading. The damage development was monitored and documented using ultrasonic C-scan, photoelastic coatings, and edge replication. A comparison of experimental fatigue results was made with those obtained with MRLife and residual strength prediction code. The static compression resistance of the AS4/3501-6 composites was found to be superior to that of the IM6/5245C laminates, and the resistance of the S2 layups was superior to that of the S12 layups. The fatigue life of the S12 layups in both the IM6 and AS4 composites was equivalent for the same cyclic loading in compression. The fatigue life of the S2 layups in the AS4 composites was lower than in the IM6 composites. The MRLife program did not satisfactorily predict the fatigue life of the composites studied under compression loading. Author (CISTI)

A CONSTITUTIVE MODEL FOR LAYERED WIRE MESH AND ARAMID CLOTH FABRIC

M. K. Neilsen, J. D. Pierce, and R. D. Krieg (Tennessee Univ., Knoxville.) Sep. 1993 65 p
(Contract DE-AC04-94AL-85000)
(DE94-003275; SAND-91-2850; TTC-1251) Avail: CASI HC A04/MF A01

A new package for the air transport of hazardous materials is currently being developed in the Transportation Systems Department at Sandia National Laboratories. The baseline design has a unique impact limiter which uses layers of aluminum screen wire and aramid cloth fabric. A primary motivation for selecting this unusual combination of materials is the need for the impact limiter to not only limit the amount of load transmitted to the primary container but also to remain in place during impact events so that it provides a thermal barrier during a subsequent fire. A series of uniaxial and confined compression tests indicated that the layered material does not behave like other well characterized materials. No existing constitutive models were able to satisfactorily capture the behavior of the layered material; thus, a new plasticity model was developed. The new material model was then used to characterize the response of air transport packages with layered impact limiters to hypothetical accidental impact events. Responses predicted by these analyses compared favorably with experiments at Sandia's rocket sled test facility in which a one-fourth scale package was subjected to side and end impacts at velocities of 428 and 650 fps, respectively. FERRITE PHASE SHIFTERS USING STRESS INSENSITIVE MATERIALS Final Report, Jul. 1991 - Jul. 1993

Todd Vaughn, Paul Cox, Gordon Harrison, and Pete Rodrigue Oct. 1993 205 p
(Contract N00014-91-C-2202)
(AD-A274639) Avail: CASI HC A10/MF A03

This R&D program sponsored by the Naval Research Laboratory and being conducted by EMS Technologies, Inc., Norcross, Georgia, is focused toward achieving improved performance in microwave switching components via use of 'stress insensitive' microwave ferrite materials for applications where stable hysteresis characteristics of the materials are critical to the RF performance. The program, therefore, primarily addresses how to relieve or improve the magnetostrictive characteristics of the materials with emphasis on the specific application and demonstration of these materials in microwave switching components, particularly ferrite toroidal phase shifters. Material investigations were focused on Mn(+3) substitutions in yttrium-gadolinium iron garnet. These compounds were evaluated in dual toroid waveguide phase shifter structures with temperature, pressure & Rf power as variables manganese substitution per formula unit for Fe+3 of 0.11 to 0.13 (2.2 to 2.6%) produced compounds which exhibited stable performance from magnetostrictive stresses in phaser structures. PROCESSING AND MECHANICAL PROPERTIES OF LAMINATED METAL COMPOSITES OF Al 6090-25 VOLUME PERCENT SiC(SUB p) AND Al 5182

C. K. Syn, D. R. Lesuer, and O. D. Sherby (Stanford Univ., CA.) 19 Mar. 1993 11 p Presented at the International Symposium on Light Materials for Transportation Systems, Kyongju, Republic of Korea, 20-23 Jun. 1993

(Contract W-7405-eng-48)
(DE94-001070; UCRL-JC-113468; CONF-9306274-1) Avail: CASI HC A03/MF A01

Multilayer laminate metal composites (LMC's) containing equal volume percent of Al 5182 and Al 6090-25 volume percent SiC(sub p) were made. The laminates were prepared by hot pressing alternate layers to a fourth of initial height at 450 C in an argon gas atmosphere. Some laminates were warm rolled by repeatedly heating to 450 C and rolling. The large plastic deformation ensured good bonding between layers. Tensile properties, fracture toughness, and damping capacity of these deformation-bonded laminates were measured. Surface descaling prior to lamination enhanced the tensile properties and toughness substantially. Post-lamination T6 heat treatment increased tensile yield and flow stress and reduced the ductility. Interfaces and dissimilar properties of the component materials enhanced the damping capacity. Yield and tensile strengths were slightly lower than values calculated from the rule of averages based on the component materials. Toughness and damping capacity were, on the other hand, far superior to those of component materials. Ductility of the laminates was increased as the layer thickness was reduced. DOE

MATERIAL OPTIMIZATION AND MANUFACTURING DEVELOPMENT OF REDUCED COST POWDER METAL TITANIUM ALLOY COMPONENTS FOR GAS TURBINE ENGINE APPLICATION, PHASE 2 Final Report, Oct. 1991 - May 1993
Stanley Abkowitz, Robert Djingheuzian, Susan M. Abkowitz, Harold Heussi, and Paul Weihrauch Nov. 1993 114 p
(Contract DAAL04-91-C-0046)
(AD-A274410; ARL-CR-110) Avail: CASI HC A06/MF A02

This Small Business Innovation Research (SBIR) program has demonstrated the economic benefits of cold-hot isostatic pressing (CHIP) powder metallurgy (P/M) materials and manufacturing technology to produce lightweight titanium alloy components. The tooling was developed, and a turbine engine bearing housing preform and a tank track pin were produced. The study also established a data base of the static and dynamic mechanical properties as a function of the chloride impurity level of the commercially available elemental titanium powders and their associated costs. INTERFACE PHENOMENA IN METAL-CERAMIC COMPOSITES Final Report, 1 May 1990 - 30 Apr. 1993
Rishi Raj 27 Sep. 1993 52 p
(Grant AF-AFOSR-0279-90)
(AD-A274167; AFOSR-93-0885TR) Avail: CASI HC A04/MF A01

This report describes theoretical and experimental results that link the properties of the heterointerface to the macroscopic mechanical behavior of metallic composites where the continuous phase is a metal and the hard phase is a ceramic (MMC's) or an intermetallic (IMC's). The results emphasize that the properties of the composites depend on the interaction between cohesive strength of the M/C or M/I interface and the physical microstructural scale of the metal. This result is general and is expected to apply from room temperature properties, such as toughness, to creep resistance at very high temperatures. At room temperature, the effect of scale is based on the dislocation pile-up model for delamination at the interface. At high temperatures, the climb rate of dislocations in the metal layer depends on its width and on the pinning efficiency of lattice dislocations at the interface. DTIC

MULTIVARIATE SPECTRAL ANALYSIS TO EXTRACT MATERIALS FROM MULTISPECTRAL DATA Final Report, Sep. 1990 - Sep. 1992
Robert S. Rand and Donald A. Davis Sep. 1993 121 p
(AD-A274142; TEC-0039) Avail: CASI HC A06/MF A02

This effort investigates various multivariate analysis techniques for classification/identification to extract natural and manmade features reliably from broad-band spectral imaging data/multispectral imagery. An enhanced Bayesian method is proposed and is demonstrated to exhibit increased accuracy over three conventional supervised classifiers. Broad-band spectral properties of various materials are examined, and the perturbations on spectra of pure materials introduced by mixtures are shown. A mixing model that uses multiple linear regression constrained by two physical properties is tested. DTIC

In the grant period just completed, the metallurgical variables identified in the previous period have been addressed. Room temperature multiaxial testing of polycrystalline NiAl has been completed and high temperature experiments are being planned. In addition, compression testing of polycrystalline NiAl at room temperature has also been done. These experiments were included in the program to further investigate the results of the multiaxial experiments. The prime objective of these experiments is to differentiate damage and plasticity observed in this material under compression. Finite element analysis based on micromechanics will be done to study the stress distribution at the grain boundaries. Together, these experiments will form the basis for development of a constitutive model which takes into consideration crystal plasticity and damage. DTIC

IMPACT TESTS ON FIBRE METAL LAMINATES UNDER A TENSILE LOAD
A. Vlot Mar. 1993 34 p
(PB94-126570; LR-714) Avail: CASI HC A03/MF A01

The well-known sensitivity of conventional composites to incidental damage, such as impact, has slowed their widespread application to thin, damage tolerance-critical primary structures such as fuselage pressure cabin skins. Therefore, impact tests were performed to determine the impact characteristics of fiber metal laminates (GLARE and ARALL). Comparative low and high velocity impact tests were performed on monolithic aluminum, fiber metal laminates, and carbon thermoplastic composites. Additional impact tests were performed on monolithic aluminum and ARALL specimens under tensile loading. NTIS

THERMOPLASTIC OR THERMOSETTING COMPOSITES IN AIRCRAFTS [TERMOPLAST-ELLER HAERDPLASTKOMPOSITER I FLYGPLANSTILLAEMPNINGAR]
O. Dickman and F. Larsson Sep. 1993 64 p In SWAHILI
(PB94-123809; FOA-A-20055-2.5) Avail: Issuing Activity (National Technical Information Service (NTIS))

This report discusses the differences in production processing and performance between thermosetting and thermoplastic fiber reinforced composites, and contains the results of a survey of the opinions of the aerospace industry, research institutes and material suppliers regarding the use of thermosets and thermoplastics. The materials considered are intended for applications as loadbearing structures and for radar camouflage in aircraft. In comparison with thermosetting resins, thermoplastics possess the advantages of high damage tolerance and low moisture absorption at high temperatures, but modified thermosetting resins have been developed with almost equal performance in these respects. Some thermoplastics have the disadvantage of being sensitive to organic solvents. Manufacture of composite components with thermoplastic matrices shows great potential for using cheap and rapid production processes, although at the present time such methods are not available for continuous fiber composites. The advantage with thermosetting resins is in the main the extensive experience and knowledge concerning production processing and performance. Anticipated new regulations for improved working environments, reduced environmentally damaging waste and increased recycling favor thermoplastics. NTIS

In the application of heat resistant composites to structural members in the high temperature atmosphere, it is very important to evaluate their mechanical behavior in high temperature atmospheres. This paper described a high temperature test system to evaluate high temperature elongation and tensile strength of heat resistant composites in the air. The preliminary strength tests of two composite materials, SiC (Silicon Carbide)/LAS (Lithium Alumino Silicate) and SiC/SiC were conducted from room temperature to 1300 C in the air using a displacement measuring system with two pairs of simple laser sensors. Avail: CASI HC A03/MF A01

The development of functionally gradient materials (FGM's) as next-generation super heat resisting materials, which can be continuously subjected to extreme environments, has been a national project in Japan since 1987. To perform computer design calculations able to determine the minimum thermal stress condition of FGM's, all the known material properties of each applied microstructure, e.g., non-FGM's, such as ceramic/metal composites, must be included in the design data base. Standard testing methods must also be developed for evaluation of mechanical properties of miniaturized samples. To evaluate the fracture strength of ceramics and ceramic/metal composites (non-FGM's), small punch (SP) tests, and for brittle materials, modified small punch (MSP) tests, have been developed to improve both specimen clamping procedures and deflection measurements. These tests enable accurate and well reproducible results to be obtained for brittle and ductile materials from room to very high temperatures, thereby enabling suitable evaluation of material properties such as Young's modulus, fracture strength, yield strength, fracture strain, and fracture energy. In addition, by utilizing SP/MSP test data from miniaturized specimens, fracture toughness values can be estimated from the correlation between fracture toughness and fracture stress. Described here are experiments carried out to standardize the SP/MSP test procedures study in order to develop a data base from which to study deflection and fracture characteristics of FGM's. Avail: CASI HC A04/MF A01

Modified small punch (MSP) method is developed for fracture characteristics evaluation of brittle materials and test results are reported. The MSP method is developed by the modification of the small punch (SP) method, which was developed to evaluate the ductility and brittleness transition temperature of ductile metal materials. Testing procedures and test results of SP method and MSP method are compared using zirconium and stainless steel composite materials. Reproducibility of test results and bending and yield strength test results from both methods are correlated. Fracture mechanisms for ceramic materials, zirconium and stainless steel composite material, and zirconium and stainless steel fiber reinforced composite material are studied by using yield strength method and MSP method together with acoustic emission test. Microscopic fracture mechanisms for these materials are also studied by the use of electronic scanning microscopic observations. Several ceramic materials and ceramic/metal composite materials at a high temperature of 1873 K are studied and test results from SP method and MSP method are compared. Author (NASDA)

HOT DEFORMATION BEHAVIOUR OF Si(p)/Al COMPOSITES AND THEIR MATRICES AND AN Al-Mg-Si ALLOY M.S. Thesis

Peter Sakaris Apr. 1993 143 p
(ISBN-0-315-84699-2; CTN-94-61089) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Research was conducted to determine the hot working behavior of an Al-Mg-Si alloy (6201), a cast Al-Si alloy (A356), and two SiC Al-matrix composites (using A356 and 6061) under continuous deformation conditions. A torsion testing method was employed since it enables a large strain to be applied to a specimen at a relatively constant rate. Stress-strain curves, fracture strains, and strain rates were determined at typical hot working temperatures. Flow stress (FS) and strain to failure (STF) data were compared to published results. The flow stresses decrease monotonically with increasing deformation temperature T. At very high temperatures, FS is similar for all materials, but as T falls to 300 C, the A356 rises more rapidly than 6061. FS for the composites rises more rapidly than the matrix alloys. The ductility of all materials increases as T increases. STF rises more rapidly for SiC/A356 than for SiC/6061 indicating that the SiC particles have much less effect as additional crack initiators in A356. Single activation energies could be computed for each material. The 6061 Al is somewhat stronger than Al because of the particles at low temperatures and the increased level of solute at high temperatures. The solutioned specimens had high peak stresses and considerable work softening at 300 C due to dynamic formation and coalescence of precipitates.

THE EXPERIMENTAL BEHAVIOR OF SPINNING PRETWISTED LAMINATED COMPOSITE PLATES Final Technical Report, 1 May 1990 - 30 Sep. 1993

John B. Kosmatka and Alex J. Lapid 1993 219 p
(Contract NCC3-173)
(NASA-CR-195220; NAS 1.26:195220; SSRP-93/10) Avail: CASI HC A10/MF A03

The purpose of the research is to gain an understanding of the material and geometric couplings present in advanced composite turbo-propellers. Twelve pre-twisted laminated composite plates are tested. Three different ply lay-ups (2 symmetric and 1 asymmetric) and four different geometries (flat and 30x pre-twist about the mid-chord, quarter-chord, and leading edge) distinguish each plate from one another. Four rotating and non-rotating tests are employed to isolate the material and geometric couplings of an advanced turbo propeller. The first series of tests consist of non-rotating static displacement, strain, and vibrations. These tests examine the effects of ply lay-up and geometry. The second series of tests consist of rotating displacement, strain, and vibrations with various pitch and sweep settings. These tests utilize the Dynamic Spin Rig Facility at the NASA Lewis Research Center. The rig allows the spin testing of the plates in a near vacuum environment. The tests examine how the material and plate geometry interact with the pitch and sweep geometry of an advanced turbo-propeller. Author (revised)

FATIGUE RESISTANCE OF UNNOTCHED AND POST IMPACT(+/- 30 DEG/0 DEG) 3-D BRAIDED COMPOSITES Final Report

Marc A. Portanova Jan. 1994 33 p
(Contract NAS1-19000; RTOP 510-02-12-09)
(NASA-CR-191590; NAS 1.26:191590) Avail: CASI HC A03/MF A01

The fatigue resistance of a multiaxial braided (3-D) graphite/expoxy composite in both unnotched and post impacted conditions has been evaluated. The material tested is a (+/- 30/0 deg) multiaxial braid constructed from AS4/12K tow graphite fibers and British Petroleum E905L epoxy resin. These materials were braided as dry preforms and the epoxy was added using a resin transfer molding process (RTM). The unnotched and post-impact specimens were tested in compression-compression fatigue at 10 Hz with a stress ratio of R=10. The unnotched tension-tension fatigue specimens were tested at S Hz with a stress ration of R=0.1. Damage initiation and growth was documented through the application of radiography and ultrasonic through transmission (C-scans). Visible inspection of surface and edge damage was also noted to describe the initiation and progression of damage in these materials. The mechanisms leading to damage initiation were established and failure modes were determined. Stiffness and strength degradation were measured as a function of applied cycles. These 3-D braided composite results were compared to strain levels currently used to design primary structure in commercial aircraft composite components made from prepreg tape and autoclave cured.

TESTING PROCEDURE FOR TOUGHNESS CHARACTERISATION OF CERAMIC MATRIX COMPOSITES

S. Yotte, J. M. Quenisset, M. Bouquet, and C. Lambert 1993 12 p
Presented at EACM, Amsterdam, Netherlands, 1992 Sponsored by Aerospatiale, France, and SEP, France
(Rept-932-430-101; ETN-94-95459) Avail: CASI HC A03/MF A01

A methodological approach of the toughness characterization of Ceramic Matrix Composites (CMC's) is proposed. The testing procedure is based on the determination of damage zone propagation curves from which an energy release rate can be derived, if a steady state propagation can be achieved. Also a parameter representative of the composite's ability to develop a damage zone can be defined during the first period of propagation. Prior to any testing, an experimental setup satisfying various procedure requirements can be defined through a three step approach: a critical examination of the testing methods commonly used for the toughness characterization of homogeneous isotropic materials; a two dimensional (2D) linear elastic analysis of the stress distribution in front of a notch tip; and a 3D numerical simulation of a toughness test while taking into account the damagable behavior of the related CMC's. A HYDROSTATIC STRESS-DEPENDENT ANISOTROPIC MODEL OF VISCOPLASTICITY

D. N. Robinson (Akron Univ., OH.), Q. Tao (Akron Univ., OH.), and M. J. Verrilli Mar. 1994 16 p
(RTOP 505-63-12)
(NASA-TM-106525; E-8651; NAS 1.15:106525) Avail: CASI HC A03/MF A01

A hydrostatic stress-dependent, anisotropic model of viscoplasticity is formulated as an extension of Bodner's model. This represents a further extension of the isotropic Bodner model over that made to anisotropy by Robinson and MitiKavuma. Account is made of the inelastic deformation that can occur in metallic composites under hydrostatic stress. A procedure for determining the material parameters is identified that is virtually identical to the established characterization procedure for the original Bodner model. Characterization can be achieved using longitudinal/transverse tensile and shear tests and hydrostatic stress tests; alternatively, four off-axis tensile tests can be used. Conditions for a yield stress minimum under off-axis tension are discussed. The model is applied to a W/Cu composite; characterization is made using off-axis tensile data generated at NASA Lewis Research Center (LeRC). Author (revised)

IMPLEMENTATION OF THERMAL RESIDUAL STRESSES IN THE ANALYSIS OF FIBER BRIDGED MATRIX CRACK GROWTH IN TITANIUM MATRIX COMPOSITES

John G. Bakuckas, Jr. (Galaxy Scientific Corp., Pleasantville, NJ.) and W. Steven Johnson Feb. 1994 44 p
(RTOP 505-63-50-04)
(NASA-TM-109082; NAS 1.15:109082) Avail: CASI HC A03/MF A01

In this research, thermal residual stresses were incorporated in an analysis of fiber-bridged matrix cracks in unidirectional and cross-ply titanium matrix composites (TMC) containing center holes or center notches. Two TMC were investigated, namely, SCS-6/Timelal-21S laminates. Experimentally, matrix crack initiation and growth were monitored during tension-tension fatigue tests conducted at room temperature and at an elevated temperature of 200 C. Analytically, thermal residual stresses were included in a fiber bridging (FB) model. The local R-ratio and stress-intensity factor in the matrix due to thermal and mechanical loadings were calculated and used to evaluate the matrix crack growth behavior in the two materials studied. The frictional shear stress term, tau, assumed in this model was used as a curve-fitting parameter to matrix crack growth data. The scatter band in the values of tau used to fit the matrix crack growth data was significantly reduced when thermal residual stresses were included in the fiber bridging analysis. For a given material system, lay-up and temperature, a single value of tau was sufficient to analyze the crack growth data. It was revealed in this study that thermal residual stresses are an important factor overlooked in the original FB models. Author

THE DEFORMATION OF COPPER-TUNGSTEN COMPOSITES Ph.D. Thesis

James Warren Poole Apr. 1993 239 p
(ISBN-0-315-84939-8; CTN-94-61111) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A series of plane strain compression experiments and finite element method (FEM) calculations was performed on continuous copper-tungsten fiber composites to examine the role of volume fraction and fiber arrangement on the mechanical behavior when the fiber axis was perpendicular to the loading direction. The flow pattern in the matrix was quantified by measuring the shape change of a fine gold grid which had been fabricated on the surface of the sample prior to deformation. It was determined that the pattern of deformation in the matrix was controlled by the spacing and geometric arrangement of the fibers. The damage process by fiber cracking or interfacial decohesion can be understood by the local distribution of stresses (as calculated by FEM) in the fibers and at the fiber matrix interface. The development of the deformation texture in the matrix and the observations of the pattern of subsequent recrystallization events can be related to the flow pattern in the matrix. The combination of careful experiments with FEM calculations was demonstrated to represent a powerful approach in studying problems involving composite materials. Author (CISTI)

Currently, the production of in situ reinforcement in polymeric systems by sol-gel methods is undergoing rapid development. However, understanding of synthesis/structure/property relationships is still lacking. In order to produce sol-gel derived composite materials with sufficient mechanical properties for commercial applications, this deficit of information must be addressed. We have completed a detailed investigation of in situ silica growth in polydimethylsiloxane (PDMS)/tetraethylorthosilicate (TEOS) systems. Factors which affect the domain growth, such as catalyst activity and silica loading, have been examined by solid state Si-29 NMR, SEM, mechanical testing, and small angle neutron scattering. DOE

CHARACTERIZATION OF ZnS-GaP NAON-COMPOSITES Ph.D. Thesis

V. Todd Dec. 1993 72 p
(Contract W-7405-eng-82)
(DE94-004888; IS-T-1669) Avail: CASI HC A04/MF A01

It proved possible to produce consistent, high-quality nanocrystalline ZnS powders with grain sizes as small as 8 nm. These powders are nano-porous and are readily impregnated with GaP precursor, although inconsistently. Both crystal structure and small grain size of the ZnS can be maintained through the use of GaP. Heat treatment of the impregnated powders results in a ZnS-GaP composite structure where the grain sizes of the phases are on the order of 10-20 nm. Conventional powder processing should be able to produce optically dense ceramic compacts with improved mechanical properties and suitable IR transmission characteristics. DOE

JOINING OF FIBRE REINFORCED METAL MATRIX COMPOSITE MATERIALS

Kazutoshi Nishimoto (Osaka Univ., Japan.) and Risto Karppi 1993 24 p
(ISSN 1235-0605)
(PB94-132453; VTT/RN-1463; ISBN-951-38-4357-2) Copyright Avail: CASI HC A03/MF A01

The joining processes of metal matrix composite materials (MMC), especially those reinforced with fibers and the problems involved in each process are briefly reviewed in the literature survey. The report focuses on the fiber reinforced aluminum matrix composites. The joining processes described include diffusion bonding, resistance welding, brazing, soldering and fusion welding. These joining processes require heating and/or pressure which tend to cause the degradation of MMC joint properties. The strength of the joint produced by any of these processes therefore remains markedly inferior to the base materials. NTIS

THE CHEMICAL DETECTOR PAPER AS A POTENTIAL ALARM

Per B. Storeboe 18 May 1993 37 p
(FFI-93/6007; ETN-94-95209) Avail: CASI HC A03/MF A01

The coloring of chemical detector paper was examined by numerical simulation. The computer program 'GAS-RISK', which is designed to compute aerosol evolution in a realistic way, was the tool used. In an operational analysis all the soldiers in a platoon were supplied with detector papers, and both on target and slightly off target chemical attacks were simulated. Rocket bursts released a fine aerosol. The performance of the paper was excellent under these conditions. The first colored paper in the position showed up before a single NAIAD, positioned in the front, gave alarm. ESA

POLYMER-BOUND RHODIUM HYDROFORMYLATION CATALYSTS Ph.D. Thesis

Tjeerd Jongsma 1992 118 p
(ETN-94-95388) Avail: CASI HC A06/MF A02

A survey of the applicability of bulky phosphite modified rhodium hydroformylation catalysts in polymer bound catalyst systems is presented. To get more insight into the catalytic cycle of this class of catalysts, a mechanistic study was carried out on the low molecular weight homogeneous tri (2-t-butylphenyl) phosphite rhodium hydroformylation catalyst. Using the information gained by this study a bulky phosphite was designed and attached to a polymer chain. The copolymer chain used to bind the ligands of the catalyst appeared to be formed by an ideally azeotropic copolymerization. This means that the ligands are perfectly randomly distributed along and among the polymer chains. This facilitates the study of the polymer bound catalyst, for the mean inter ligand distance can directly be related to the polymer chain loading. The bulky phosphite ligand used yielded active catalysts and no decrease of activity was observed when the catalyst was attached to the polymer chain, but the coordination constant of the ligand for rhodium was too low for application of this system in continuous flow reactors. A slightly smaller phosphite, which forms bis-phosphite rhodium complexes, was used in the proceeding studies. A closer examination of the influence of the polymer chain in the complex formation and activity of the copolymer bound catalyst was performed. Especially the dependency of the complex formation on the chain loading alpha (phosphite comonomer fraction) is studied. An X-ray study of the low molecular weight bis-phosphite rhodium complex was performed and proved to be of great help in understanding the sterical conformation of low molecular weight as well as polymer bound rhodium phosphite complexes. The polymer bound catalyst was grafted on an inert silica sphere. The so formed silica grafted polymer bound catalyst system was successfully used in a continuous flow reactor for the hydroformylation of styrene. ESA

ON THE THERMAL IGNITION WITH VARIABLE PRE-EXPONENTIAL FACTOR
S. S. Okoya Oct. 1992 9 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-616009; IC-92/337) Avail: CASI HC A02 (US Sales Only)

This work is concerned with the exothermic chemical reaction, taking the diffusion of the reactant into account and assuming an Arrhenius temperature dependence with variable pre-exponential factor. Of particular interest is the Frank-Kamenetskii parameter delta which we explicitly obtained in terms of the dimensionless activation number epsilon and the peak temperature excess theta(sub m) under physically reasonable assumptions. UV ABSORPTION TECHNIQUE FOR MONITORING MOBILE SOURCE NO EMISSIONS Final Report, 1 Oct. 1992 - 30 Sep. 1993
R. P. Howard and W. J. Phillips Nov. 1993 20 p
(AD-A273858; AEDC-TR-93-18) Avail: CASI HC A03/MF A01

Ultraviolet (UV) absorption techniques developed and used by the Arnold Engineering Development Center (AEDC) for measurements of nitric oxide (NO) in exhaust flows of turbine and liquid-propellant rocket engines were adapted for measurements of NO in the exhausts of automobiles. Measurements were performed across a roadway with a 10-percent mixture of NO being released into the exhaust stream of a small truck traveling at speeds ranging from 6 to 30 mph. Emission factors for these simulated exhausts ranged from 0.92 to 23.05 gm/mi. Nitric oxide was detected in measurements using NO-resonance lamp radiation passed twice across the roadway for emission factors as low as 1.78 gm/mi. Nitric oxide absorption was not detected on exhaust measurements of automobiles traveling (coasting) at constant speeds. Nitric oxide was detected at measurable levels on automobiles forced to stop and then accelerate through the measurement station. DTIC

Thompson, V. B. Campbell, A. L. Glover, and J. M. Googin 1993 15 p Presented at the Annual Vacuum Society Science Symposium, Triangle Park, NC, 15-19 Nov. 1993
(Contract DE-AC05-84OS-21400)
(DE94-002754; Y/DV-1298; CONF-9311110-1) Avail: CASI HC A03/MF A01

In a microwave electron cyclotron resonance (ECR) plasma source, reactive plasmas of oxygen and its mixture with argon are used for plasma-cleaning experiments. Aluminum test samples (0.95 x 1.9 cm) were coated with thin films (less than or equal to 20 (mu)m in thickness) of Shell Vitrea oil and cleaned by using such reactive plasmas. The plasma cleaning was done in various discharge conditions with fixed microwave power, RF power, biased potential, gas pressures (0.5 and 5 mtorr), and operating time up to 35 min. The status of plasma cleaning has been monitored by using mass spectroscopy. Mass loss of the samples after plasma cleaning was measured to estimate cleaning rates. Measured clean rates of low pressure (0.5 mtorr) argon/oxygen plasmas were as high as 2.7 (mu)/min. X-ray photoelectron spectroscopy was used to determine cleanliness of the sample surfaces and confirm the effectiveness of plasma cleaning in achieving atomic levels of surface cleanliness. In this paper, significant results are reported and discussed. DOE

THE USE OF ON-LINE ION CHROMATOGRAPHY FOR HIGH TEMPERATURE AND HIGH PRESSURE REACTION STUDIES
Garry J. Lynch Oct. 1993 26 p Presented at the Pittsburgh Conference on Analytical Chemistry and Applied Spectroscopy, Chicago, IL, 28 Feb. - 4 Mar. 1994
(Contract DE-AC11-93PN-38195)
(DE94-002525; WAPD-T-3009; CONF-940209-1) Avail: CASI HC A03/MF A01

This paper describes the use of on-line ion chromatography as a tool for chemistry reaction studies in small volume systems. The technique was used to study chemistry behavior in a high temperature and high pressure autoclave system. A dual analyzer, multi-channel on-line ion chromatograph (IC) was configured to automate the sampling and analysis. Analytical channels were set up for analysis of inorganic anions, monovalent cations, conductivity, and pH. Conductivity and pH were measured using the IC as a flow injection analyzer. Use of the IC system provides significant advantages over conventional sampling and analysis techniques: Reduction in sample volume, a closed sampling system that protects air or light sensitive analytes from breakdown, around-the-clock test performance combined with automatic calibration and quality control checking, and detection and tracking of reaction products or unexpected contaminants. Methods used to correct measured concentrations for the effects of sampling and for calculation of control chemical loss half-lives are presented. A limited evaluation of the flow injection analysis methods for conductivity and pH is provided. DOE

CHARACTERIZATION OF ACOUSTIC EFFECTS ON FLAME STRUCTURES BY BEAM DEFLECTION TECHNIQUE
B. Bedat, L. W. Kostiuk, and R. K. Cheng Oct. 1993 12 p Presented at the Fall Meeting of the Western States Section of the Combustion Institute, Menlo Park, CA, 18-19 Oct. 1993
(Contract DE-AC03-76SF-00098)
(DE94-003240; LBL-34700; CONF-931076-3) Avail: CASI HC A03/MF A01

This work shows that acoustic effects are the cause of the small amplitude flame wrinkling and movements seen in all the different gravitational conditions. The comparison between the acoustic velocity and beam deflection spectra for the two conditions studied (glass beads and fiber glass) demonstrates clearly this flame/acoustic coupling. This acoustic study shows that the burner behaves like a Helmholtz resonator. The estimated resonance frequency corresponds well to the experimental measurements. The fiber glass damps the level of the resonance frequency and the flame motion. The changes shown in normalized beam deflection spectra give further support of this damping. This work demonstrates that the acoustics has a direct influence on flame structure in the laminar case, and the preliminary results for the turbulent case also show a strong coupling. The nature of this flame/acoustic coupling are still not well understood. Further investigation should include determining the frequency limits and the sensitivity of the flame to acoustic perturbations. DOE

The goal of this project is to carry out the fundamental researches for the selective photoionization process of heavy atoms as well as the development of experimentally related instruments. Main research results carried out in this year are (1) multi-step photoionization spectroscopy of Hg atom by 3-color 3-step ionization scheme, (2) selective photoionization using polarization spectroscopy, (3) design and construction of ion separator chamber, and (4) theoretical study for spectroscopic parameters of mercury. This technology can be applied to several area of nuclear industry such as the utilization of radioactive waste, the development of new materials, and high sensitive analysis of heavy atomic elements. FERMI-LIQUID TO NON-FERMI-LIQUID TRANSITION IN A DYNAMICAL GENERALIZATION OF THE CPA IN A DISORDERED HUBBARD MODEL
I. Dasgupta and A. Mookerjee Jul. 1993 13 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-601875; IC-93/213) Avail: CASI HC A03 (US Sales Only)

Based on the augmented space formalism and a generalization of the alloy analogy, including the effect of the dynamics of the exchange bath, it is shown that a half-filled Hubbard model shows Fermi-liquid behavior at low values of the interaction parameter U. This gives way to non-Fermi liquid behavior at a critical U, where the system is still metallic. It is also shown that quenched disorder tends to lower this critical value of U. DOE

NEUTRON REFLECTION INTERFEROMETRY
V. P. Gudkov, G. I. Opat, and A. G. Klein 12 May 1993 20 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-601876; UM-P-93/19) Avail: CASI HC A03 (US Sales Only)

It is shown that the analysis of stratified surface layers by neutron reflection interferometry is considerably enhanced by performing the reflectometry with phase information. Two methods of providing such information are presented. One is the Lloyd's mirror configuration, in which a directly propagating ray that interferes with the reflected ray supplies the phase information. The method has much in common with holography. The other is by the physical addition of an extra reference layer, whose amplitude and phase are known theoretically. It is concluded that in addition to the large intensity of the reflected neutron beam, the total reflection gives an analytical relation between phase of the reflection coefficient and the density distribution. This gives rise the possibility of obtaining density distributions near surfaces in a model independent way. Moreover, a comparison is possible of reflective coefficients from original and artificially layered surfaces, provided that the thickness of the layer is small enough. DOE

THEORETICAL DETERMINATION OF CHEMICAL RATE CONSTANTS USING NOVEL TIME-DEPENDENT METHODS Final Technical Report, 1 Jan. 1991 - 31 Jan. 1994
Christopher E. Dateo 12 Mar. 1994 7 p
(Contract NCC2-737)
(NASA-CR-195221; NAS 1.26:195221) Avail: CASI HC A02/MF A01

The work completed within the grant period 10/1/91 through 12/31/93 falls primarily in the area of reaction dynamics using both quantum and classical mechanical methodologies. Essentially four projects have been completed and have been or are in preparation of being published. The majority of time was spent in the determination of reaction rate coefficients in the area of hydrocarbon fuel combustion reactions which are relevant to NASA's High Speed Research Program (HSRP). These reaction coefficients are important in the design of novel jet engines with low NOx emissions, which through a series of catalytic reactions contribute to the deterioration of the earth's ozone layer. A second area of research studied concerned the control of chemical reactivity using ultrashort (femtosecond) laser pulses. Recent advances in pulsed-laser technologies have opened up a vast new field to be investigated both experimentally and theoretically. The photodissociation of molecules adsorbed on surfaces using novel time-independent quantum mechanical methods was a third project. And finally, using state-of-the-art, high level ab initio electronic structure methods in conjunction with accurate quantum dynamical methods, the rovibrational energy levels of a triatomic molecule with two nonhydrogen atoms (HCN) were calculated to unprecedented levels of agreement between theory and experiment. USE OF OXYGEN-17 ISOTOPE IN THE CHARACTERIZATION OF ZEOLITES AND RELATED STRUCTURES BY NUCLEAR MAGNETIC RESONANCE SPECTROSCOPY
Aila Maijanen, Arto Annila, Pia Qvintus-Leino, and Anneli Hase Apr. 1993 29 p Sponsored by Neste Foundation, Finland
(ISSN 1235-0605)
(VTT-TIED-1448; ISBN-951-38-4350-5; ETN-94-95266) Copyright Avail: CASI HC A03/MF A01

Solid state Nuclear Magnetic Resonance (NMR) spectroscopy is a powerful tool in the structure determination of zeolites. The current status of the use of O-17 NMR in the characterization of zeolites and related structures is surveyed. All the major components of zeolites contain an NMR active isotope: Si-29, Al-27 and O-17. The natural abundance of O-17 is low (0.037%), and thus, it requires enrichment of the sample with O-17 isotope. O-17 is a quadrupolar nucleus and the qadrupolar interaction broadens and shifts the NMR signal. Thus, in order to get higher resolution, a high static magnetic field and magic angle spinning technique with high spinning frequency should be used. Dynamic angle spinning and double rotation techniques were shown to improve the resolution of O-17 NMR spectra. Lineshape simulations are necessary to determine the O-17 NMR parameters of quadrupolar interaction. ESA

MOLTEN SALT TECHNIQUES FOR REPRODUCIBLE EXCESS HEAT Final Report
Bor Y. Liaw 5 Jan. 1994 4 p

(Contract N00014-92-J-1673)
(AD-A274935) Avail: CASI HC A01/MF A01

Major accomplishments were electrochemical characterization of Ni electrode system in the hydride-containing molten salts and calorimetry measurements of anomalous temperature excursion in the electrolysis of the Ni-H-based molten salt systems. The excess heat generation in molten salt systems is progressing well through the increasing understanding of electrochemical behavior of the cell and the availability of a variety of electrode materials used in the cell. Several issues are still open for improvements: the control of the cell behavior, the integrity of anode materials, the role of impurities in excess heat generation, and the threshold loading at elevated temperatures - just to name a few. ZINC(2) OXIDE STABILITY IN ALKALINE SODIUM PHOSPHATE SOLUTIONS AT ELEVATED TEMPERATURES
S. E. Ziemniak and E. P. Opalka Apr. 1993 29 p
(Contract DE-AC12-76SN-00052)
(DE94-003316; KAPL-4762) Avail: CASI HC A03/MF A01

Zinc oxide (ZnO) is shown to transform into either of two phosphate-containing compounds in relatively dilute alkaline sodium phosphate solutions at elevated temperatures via ZnO(s) + Na(+) + H2PO4(-)) (r reversible) NaZnPO4(s) + H2O or 2 ZnO(s) + H3PO4(aq) (r reversible) Zn2(OH)PO4(s) + H2O. X-ray diffraction analyses indicate that NaZnPO4 possesses an orthorhombic unit cell having lattice parameters a = 8.710 (+/-) 0.013, b = 15.175 (+/-) 0.010, and c = 8.027 (+/-) 0.004 A. The thermodynamic equilibria for these reactions were defined in the system ZnO-Na2O-P2O5-H2O for Na/P molar ratios between 2.1 and 3. Based on observed reaction threshold values for sodium phosphate concentration and temperature, the standard entropy (S deg) and free energy of formation ((Delta)G(sub f)(sup deg)) for NaZnPO4 were calculated to be 169.0 J/mol-K and -1510.6 kJ/mol, respectively; similar values for Zn2(OH)PO4 (tarbuttite) were 235.9 J/mol-K and -1604.6 kJ/mol. Additions of sodium sulfite and sulfate did not alter the above reactions. DOE

TRANSITION METAL ACTIVATION AND FUNCTIONALIZATION OF CARBON-HYDROGEN BONDS
1993 3 p
(Contract DE-FG02-86ER-13569)
(DE94-003650; DOE/ER-13569/8) Avail: CASI HC A01/MF A01

A method was developed for synthesizing a new complex for studying C-H activation, (HBPz*(sub 3))Rh(CNCH2CMe(sub 3))(PhN=C=NCH2)CMe(sub 3). This complex loses the carbodiimide ligand, thereby serving as a precursor for a 16-electron Rh(I) fragment which activates (via oxidative addition) a wide range of aromatic and aliphatic C-H bonds. The mechanism of activation of benzene by this fragment was studied. Reaction of (Tp'Rh(CNR)) fragment with aliphatic hydrocarbons was also studied. A study of C-H bond activation by the complex MnH3(dmpe)(sub 2) was completed. Reactions of (Ru(dmpe)(sub 2)) with several small molecules were also investigated. Effects of fluorine substituents on aromatic ring on C-H activation were looked at. Studies of (eta)(sup 2)-arene coordination with ((C5Me(sub 5))Rh(PMe(sub 3))) were completed; studies of reaction of this complex with 1,3-disubstituted benzenes are in progress. DOE

STRUCTURE OF IONIC FLUIDS IN EQUILIBRIUM WITH A MICROPOROUS IONIC MATRIX
H. Tatlipinar, G. Pastore (Trieste Univ., Italy.), and M. P. Tosi (Scuola Normale Superiore, Pisa, Italy.) Jul. 1993 10 p
(DE94-600563; IC-93/205) Avail: CASI HC A02/MF A01 (US Sales Only)

The Ornstein-Zernike equations for the structure of a fluid of positive ions in equilibrium with a disordered matrix formed by chlorine ions are solved numerically in the hypernetted-chain approximation, and the results are compared with those obtained for the corresponding molten salt at complete equilibrium. Quenching of the halogen frame in a model appropriate to CuCl enhances the delocalization of the Cu ions. A similar, though less striking, reduction in the short range order of the metal-ion components is accompanied by an enhancement of its state of intermediate-range order in models appropriate to trivalent metal halides with octahedral or tetrahedral-type coordination. The research and development activities of the Radiochemistry Division during 1991 are briefly described under the headings: (1) Nuclear chemistry, (2) Actinide chemistry, and (3) Spectroscopy. In the field of nuclear chemistry, the main emphasis has been on the studies of fission process induced by reactor neutrons and light and heavy ions on actinides and low Z (Z less than 80) elements. Actinide chemistry research work deals mostly with studies on the solvent extraction behaviour of actinide and lanthanide ions from aqueous media using different organic reagents including CMPO and macrocyclic ligands. The spectroscopic studies include development of methods for the estimation of trace metallic impurities and rare earths in nuclear fuel materials and EPR investigations of high T(sub c) superconductors. A list of publications by the scientific staff of the Division is given at the end. DOE

TEMPLATE SYNTHESIS OF METAL MICROTUBULE ENSEMBLES UTILIZING CHEMICAL, ELECTROCHEMICAL, AND VACUUM DEPOSITION TECHNIQUES Interim Report
Charles J. Brumlik, Charles R. Martin, and Vinod P. Menon 3 Jan. 1994 37 p
(Contract N00014-82-K-0612)
(AD-A274676; TR-90-ONR) Avail: CASI HC A03/MF A01

Microtubules are an interesting type of microstructure that resemble miniature drinking straws. Such tubular microstructures are found in nature. In addition, we and others have been investigating strategies for making synthetic analogs. We are especially interested in the idea of making metal microtubules. Four procedures for preparing metal microtubules are described in this paper. The general approach, called template-synthesis, entails using the pores in a microporous membrane as templates for forming the tubules. Microporous anodic aluminum oxide membranes and nuclear track-etch membranes are used as the template membranes. Gold and silver microtubules are made with outer diameters as small as 200 nm. These microstructures are characterized by scanning electron microscopy. DTIC

A MIMIC MODEL OF Pt-Rh CATALYST PREPARED BY ELECTROCHEMICAL DEPOSITION OF Rh ON Pt (100) SURFACE
Masahiro Taniguchi, Erik K. Uzembaev, and Kenichi Tanaka Mar. 1993 22 p Sponsored by Ministry of Education, Science and Culture, Tokyo, Japan
(ISSN 0082-4798)
(Rept-A-2664; JTN-94-80535) Avail: CASI HC A03/MF A01

Electrochemical deposition of Rh ions on a (5 x 20) Pt (100) surface gave the (1 x 1) LEED (Low-Energy Electron Diffraction) pattern with high back ground intensity. By exposing the (1 x 1) Rh/Pt (100) surface to O2 or NO, a characteristic p (3 x 1) Rh-O overlayer is built up at about 400

K, which is the same structure observed on the Pt(0.25) Rh(0.75) (100) surface exposed to NO or O2. Once the p(3 x 1) Rh-O overlayer is formed, a reversible structural change, p(3 x 1) = (1 x 1), can be caused at room temperature by adding H2 and O2. The p(3 x 1) Rh-O overlayer on Pt (100) surface may represent a highly efficient catalyst for NO(x) reduction. Author (NASDA)

AN APPARATUS FOR MEASUREMENT OF IGNITION AND BURNING CHARACTERISTICS OF METALLIC PARTICLES M.S. Thesis
Stephen Gulakowski 17 Sep. 1993 36 p
(AD-A274815) Avail: CASI HC A03/MF A01

An apparatus was designed for use in determining ignition and combustion characteristics of metallic fuel particles and liquid fuel droplets. The design was tailored around the available data acquisition systems and diagnostic instruments. The apparatus consisted of a small windowed combustion bomb, a CO2 laser for particle ignition, a thermal imaging camera for recording the ignition process, a helium-neon laser and a 1024 element linear diode array sampled at 1Mhz for measuring forward scattered light and determining particle size (Fraunhofer diffraction). All major components were individually utilized. However, equipment limitations prevented actual use of the system for measurement of the burning rates of particles. Recommendations are made which would permit the original objectives to be met. DTIC

In this study, we have characterized the phosphogypsum from the industrial phosphoric acid of Annaba chemical plant (Algeria). This procedure was achieved by x-ray diffraction in order to know different forms of sulphates contained in the phosphogypsum before its treatment. After chemical treatment, we have identified qualitatively the rare earth by x-ray fluorescence spectrometry. DOE

(NASA-CR-195213; NAS 1.26:195213) Avail: CASI HC A02/MF A01

The goal of this program was to develop an understanding of heterogeneous kinetic processes for those molecular species which produce gaseous hydrogen degradation of the mechanical properties of metallic structural materials. Although hydrogen degradation of metallic materials is believed to result from dissolved protonic hydrogen, the heterogeneous hydrogen interface transport processes often dominate the kinetics of degradation. The initial step in the interface transport process is the dissociative chemisorption of the molecular species at the metal surface followed by hydrogen absorption into and transport through the bulk. The interaction of hydrogen with the surfaces of alpha-2(Ti3Al) titanium aluminide, gamma(TiAl) titanium aluminide, and beryllium were studied. Author (revised)

(DE94-003158; DOE/ER-13996/4) Avail: CASI HC A01/MF A01

Confocal Raman microscopy was developed and used to study molecular sulfur inclusions in glass pellets. The Raman spectrum of water was used as a noninvasive temperature probe in operating electrophoresis capillaries. A macro-scale imager was used to image water Raman scattering using 30 mW 532 nm. The imager can be used to map boundaries, impurity distributions, and morphological changes in polymers and ceramics. A holographic beam splitter was obtained. Surface-enhanced Raman spectra was obtained from inside zebra fish embryos as a model system. Future research plans are given. DOE

The penetration depths possible with near-infrared spectroscopy make it well suited for reagentless monitoring of analytes in body fluids or noninvasive monitoring of human tissue. As an initial step in achieving these goals, we have conducted near-infrared in-vitro experiments of dilute aqueous solutions containing analytes of physiological importance. By combining partial least squares (PLS) multivariate calibration methods with Latin Hypercube statistical design, we have obtained precise near-infrared spectral determinations of urea, creatinine, and NaCl in dilute aqueous solutions. Cross-validated PLS calibrations for the three analytes and temperature were very precise and resulted in R(exp 2) values greater than 0.997. DOE

MODERN PHOTOACOUSTIC SPECTROSCOPY PROBLEMS. THEORY AND EXPERIMENT (A REVIEW)
G. S. Mityurich (Gomel Polytechnic Inst., USSR.), J. Motylewski, and J. Ranachowski 1993 164 p
(ISSN 0208-5658)
(IFTR-41/1993) Avail: CASI HC A08/MF A02

The review presents investigation of photoacoustic transformation in condensed media, including naturally gyrotropic and magnetoactive substances. The analysis is performed on numerous theoretical models of linear as well as nonlinear sound generation mechanism. Sound wave excitation is assumed to be amplitude or polarization-modulated light beam. The potentiality of linear and circular dichroism parameters determination by means of photoacoustic and photodeflectional spectroscopy is evaluated. The experimental stands for subsequent gyrotropic media investigation in IFTR are described. Author

(AD-A274609) Avail: CASI HC A03/MF A01

The 1993 Gordon Research Conference on the Physics and Chemistry of Laser Diagnostics in Combustion was held at Plymouth State College (South) in Plymouth, New Hampshire, July 12-16, 1993. This conference is primarily concerned with the fundamental physics and chemistry underlying the wide variety of laser-based optical spectroscopic diagnostic techniques which are used for studying combustion processes. The focus is on in-situ and nonperturbing optical methods for one-, two-, and three-dimensional measurements of species concentrations, temperature, and velocity. The development of such quantitative methods using linear and nonlinear optical interactions encompasses a broad scope of interdisciplinary research including basic and applied physics and chemistry. The NIST Annual Conference on Fire Research has long been a prime forum for presentation and discussion of the latest advances in fire science and engineering. The conference includes mostly fire research performed within Federal laboratories, or sponsored by Federal agencies. However, some private sector and foreign fire research is also included. This year's conference focuses on the development, verification of fire safety engineering tools, and their application to building fires, transportation fires, underground fires, and large fires. This will enable scientists and engineers to describe recent work on fire models and measurement methods and users to describe experiences and limitations in the use of these tools. NTIS

(DE94-001385; BNL-49457; CONF-921101-139) Avail: CASI HC A02/MF A01

Poly(carbon disulfide) was studied by cyclic voltammetry using glassy carbon and platinum macro- and microdisk electrodes. The electron transfer kinetics is significantly faster at glassy carbon electrodes than at Pt electrodes. It is chemically reversible with moderate electron transfer rates. Voltammetric results of poly(carbon disulfide) are in good agreement with battery testing data. The k(sup 0) value measured at a Pt microdisk electrode is 7 x 10(exp 3) cm/sec. Electrochemical data suggest that PCS can be a potential cathode material for low current density lithium batteries. DOE

The spherical harmonics (P(sub N)) approximation of radiative transfer equation, which is mathematically rigorous and can take into account of anisotropical scattering, is extended to a case where radiative properties are variable in a three-dimensional enclosure. Next the monochromatic optical properties of ash polydispersions in coal combustion gas are estimated intending to realize actual conditions. As an example of numerical analyses light scattering and absorbing effects by ash polydispersions in the coal-fired Magnetohydrodynamics (MHD) combustion gas are predicted and compared with the experimental results obtained in a laboratory-scale test duct. Also spectral emissions particular to the coal-fired MHD combustion gas are clarified and the wing reversal method to minimize the self-resonance absorption error in measurement of main-stream gas temperature and potassium number density is studied analytically and experimentally in the far-wing wavelength region. Experimental and theoretical contributions were made to advance our understanding of the chemical reaction mechanism of natural gas combustion. A radically different technology of mechanism development was shown to be needed in order to progress toward parameterizations of the detailed reaction mechanism that will be suitable for calibrating the reduced-variable mechanisms required for fluid dynamics computer codes. Experimental support of the mechanism development was provided by shock tube investigations of the profiles of OH, CO, CH3 and CH3O intermediates that play key roles in the combustion process. NTIS

REACTIVITY OF NITRATE RADICAL (NO3) TOWARD ORGANIC COMPOUNDS [NAITORETO RAJIKARU (NO3) NO YUKIBUTSU NI TAISURU HANNOSEI] **c23**
Osamu Ito *In its* Bulletin of the Institute for Chemical Reaction Science, Tohoku University, Volume 2 30 Sep. 1992 p 15-31 In JAPANESE (For primary document see N94-27385 07-25)
Avail: CASI HC A03/MF A02

A method to evaluate the reaction rate constants for the reactions of the nitrate radical with various organic compounds in organic solution by applying the flash photolysis method is outlined. For many organic compounds, the reaction rate constants in the solution are greater than those in the gas phase by factors of 50 to 100. This finding indicates that the electronic structure of the nitrate radical in solution is quite different from that in the gas phase. By the comparison of the absolute rate constants, it is clearly indicated that the reaction modes of the nitrate radical are dependent on the reactants. For the compounds with hydrogen having high ionization potentials, the hydrogen atom abstraction is the main route; for compound with double bonds, the addition mode becomes predominant. For organic compounds with low ionization potentials, the electron transfer reaction occurs even though they have considerably active hydrogen. The reaction modes are also clearly shown by transient absorption bands which are secondly produced by the reaction of the nitrate radical with substrates. The sulfur compounds exhibit a variety of the reaction mechanism depending on the oxidation state of the sulfur, which affords a good example for the interchange of the reaction routes.

FOUR PHASE MICROWAVE PULSE GENERATOR FOR PULSED EPR SPECTROMETER [PARUSU EPR YO 4 ISO MAIKUROHA PARUSU HASSEIKI NO SHISAKU] **c33**
Yasunori Ohba, Rie Satoh, and Masamoto Iwaizumi *In its* Bulletin of the Institute for Chemical Reaction Science, Tohoku University, Volume 2 30 Sep. 1992 p 33-37 In JAPANESE (For primary document see N94-27385 07-25)
Avail: CASI HC A01/MF A02

In NMR (Nuclear Magnetic Resonance), pulsed-FT (Fourier Transformation) is superior to CW (Continuous Wave) method in respect to sensitivity and multidimensional spectrum. When pulsed-FT is applied to EPR (Electron Paramagnetic Resonance) high resolution can be achieved in addition to the advantages in NMR, so that it is useful to study intermediates of chemical reaction. Pulsed-FT enables to excite entire spectrum by one pulse, however, it is difficult to cover the whole EPR spectrum zone. Therefore, QD (Quadrature Detection) which detect EPR signal at the phase of 0 and 90 degrees to the reference signal is applied in EPR. This enables us to double the observation spectrum zone, and improve S/N (Signal to Noise) ratio and pulse power efficiency, because QD can distinguish frequency of EPR signal from that of excitation microwave. In order to apply QD in ESR (Electron Spin Resonance), it is important to balance the two phases (0 and 0 degrees), although it is difficult in frequency range used in X band region of EPR. The CYCLOPS (Cyclically Ordered Phase Sequence) which can correct EPR signals by FID (Free Induction Decay) measured by four phase (0, 90, 180, 270 deg) microwave pulses is useful to obtain well-balanced phases. In this study, a four phase microwave pulse generator for X band region was manufactured, and the performance of it was discussed.

VARIABLE TEMPERATURE COLD STAGE FOR MICROSCOPE OBSERVATION [ONDO KAHEN KENBIKYO TEION SUTEJI NO SHISAKU] **c35**
Hirosi Yamada, Minoru Hanaya (Tokyo Inst. of Tech., Japan.), Youichi Kanno, Takemitu Kikuchi, and Shinji Onodera *In its* Bulletin of the Institute for Chemical Reaction Science, Tohoku University, Volume 2 30 Sep. 1992 p 39-40 In JAPANESE (For primary document see N94-27385 07-25)
Avail: CASI HC A01/MF A02

It is considerably important to measure crystallization velocity in vitreous state for understanding of crystallization mechanism and quantitative analysis of crystallization process. For this measurement, a microscope equipped with a variable temperature cold stage is useful to regulate temperature to be constant for a long period because some crystallization takes a long time around glass transition point. However, since conventional cold stages are cooled by liquid nitrogen gas flow, it is difficult to cool continuously for a long time and to regulate the temperature accurately. This report presents a cold stage cooled by methanol flow which can control the temperature of samples accurately. The device consists of the microscopic stage cooled by cold methanol flow equipped with a thermocouple to regulate the temperature. As a result, this device makes it possible to observe a specimen within the range of 200 to 260 K with deviation of 0.05 K for one month. Therefore, very slow crystallization in low temperature can be measured by this device.

GLASS CYLINDRICAL FILTER FOR ELECTROLYSIS CELL [DENKAISOYO GARASU ENTO FIRUTA NO SEISAKU] **c35**
Shinichi Abe and Fuminori Akiyama *In its* Bulletin of the Institute for Chemical Reaction Science, Tohoku University, Volume 2 30 Sep. 1992 p 47-48 In JAPANESE (For primary document see N94-27385 07-25)
Avail: CASI HC A01/MF A02

Some electrolysis requires separation of electrolytic solution by a filter between two electrodes in order to prevent products from reacting secondarily at another electrode. These filters are usually made of a glass filter or ion exchanger membrane, and they are fixed at the electrolysis cell or cover one electrode. This report presents a detachable glass cylindrical filter for electrolytic reaction. The glass cylindrical filter was made from glass filter powder placed in a mold and heated at 800 C for 18 minutes. Using this filter, electrolytic reduction of carbon dioxide was performed in 0 C hot water with benzoin. This reaction produces aqueous oil from carbon dioxide and water. The products were compared with and without the filter and, although the yield did not differ between the two reaction systems, products without the filter contained highly polymerized oil compared to those with the filter. This suggests that the aqueous oil was produced at the cathode and polymerized at the anode.

POROUS VYCOR GLASS TUBE JOINED TO BOROSILICATE GLASS [TAKOSHITSU BAIKORU GARASUKAN NO YOSETSU] **c35**

Shinichi Abe, Takemitsu Kikuchi, and Shinji Onodera *In its* Bulletin of the Institute for Chemical Reaction Science, Tohoku University, Volume 2 30 Sep. 1992 p 49-50 In JAPANESE (For primary document see N94-27385 07-25)
Avail: CASI HC A01/MF A02

Porous glass can absorb various size of molecules with large surface area even in high temperature. However, it is difficult to use porous glass tubes at high-temperature, for example as a separation membrane for hydrogen condensation, because adhesives at joining sites could be damaged. In this study, welding of a porous glass tube and a glass tube was attempted to develop a gas separation membrane used at 500 C. Since forms present in porous glass may cause crack at high temperature, it is necessary to remove such forms by heat processing. Such porous glass is called to be porous vycor glass, which contains quartz 6 percents, and can be joined with a quartz tube. As a result, a gas separator with porous glass membrane which is joined by this process could endure high temperature up to 600 C and could maintain high vacuum. Author (NASDA)

(DE94-004236; DOE/CE-23810/22A) Avail: CASI HC A03/MF A01

Numerous fluids have been identified as promising alternative refrigerants, but much of the information needed to predict their behavior as pure fluids and as components in mixtures does not exist. In particular, reliable thermophysical properties data and models are needed to predict the performance of the new refrigerants in heating and cooling equipment and to design and optimize equipment to be reliable and energy efficient. The objective of this project is to provide highly accurate, selected thermophysical properties data for refrigerants HFC-143a, CH_3CF_3, and HFC-152a, CH_3CHF_2, and to use these data to fit complex equations of state and detailed transport property models. The new data will fill gaps in the existing data sets and resolve problems and uncertainties that exist in and between the data sets. DOE

NOVEL OXIDIZING REAGENTS DERIVED FROM ELEMENTAL FLUORINE Ph.D. Thesis
Moshe Kol Aug. 1991 165 p In HEBREW
(ITN-94-85231) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

Two novel fluorine-derived oxidizing systems were studied: hypofluorous acid in acetonitrile, and methyl hypofluorite. This research is part of a program aimed at introducing fluorine into organic synthesis methodology. Nuclear magnetic resonance (NMR) and mass spectrometer measurements of an oxidizer formed by passing nitrogen-diluted fluorine through a solution of water in acetonitrile proved the oxidizer to be a complex of hypofluorous acid and acetonitrile. A wide-range study of the reactions of the above oxidizer with electron-rich systems was performed. Both of the hypofluorite systems studied were found to be powerful oxidants which made possible a variety of transformations under mild conditions. ISA

PRESSURE-GAIN COMBUSTION
G. A. Richards, J. Yip, R. S. Gemmen, M. C. Janus, T. Norton, and W. A. Rogers 1993 9 p Presented at the Joint Contractors Meeting on Advanced Turbine Systems, Fuel Cells and Coal-Fired Heat, Morgantown, WV, 3-5 Aug. 1993
(DE94-002975; DOE/METC-C/94/7106; CONF-930893-39) Avail: CASI HC A02/MF A01

Pulse combustion has been proposed for gas turbine applications in many early articles and more recently has been demonstrated to produce so-called 'pressure-gain' in a small gas turbine. The basic concept is that the oscillatory combustion occurs as a constant-volume process, which produces a gain in the stagnation pressure of air flowing through the combustor, rather than the pressure loss associated with conventional, steady combustion. If properly utilized, this pressure-gain could enhance simple-cycle gas turbine efficiency several percent depending on the operating conditions. In addition, pulse combustors have demonstrated relatively low NO(x) pollutant levels in some applications. The combined potential for higher cycle efficiency and lower pollutant levels is the basis for the present investigation. Tests in progress at the Morgantown Energy Technology Center (METC) have considered a baseline pulse combustor configuration that has shown good oscillating performance, low NO(x) emissions, but disappointing results in terms of pressure-gain. However, a combination of numeric simulations and test data suggest that pressure-gain can be produced by a select combination of operating conditions and combustor geometry, but is especially sensitive to the combustor inlet geometry. Tests in progress will evaluate the effect of inlet geometry and operating pressure on both pollutant emissions and pressure-gain. DOE

The workshop on hydrogen bond was restarted changing its name to 'Hydrogen Physics' for grasping hydrogen bond from a wider viewpoint and expecting the new development in this field hereafter. As the basic attitude, the phenomena related to hydrogen bond are reviewed from two different systems: hydrogen-lattice system and hydrogen-electron system. The Hydrogen Physics meeting was held on September 29 and 30, 1992, at National Laboratory for High Energy Physics, and 19 lectures were given. The themes were proton dynamics of hydrogen bond, water science and water with good taste, collective movement and fluctuation of water, neutron diffraction of water, hydrogen bond in water as seen from Raman scattering, electron and proton movements in organic crystals, new deuterium substitution effect of proton transfer in hydrogen bond in solids, infrared spectroscopy for one-dimensional hydrogen bond crystals, MSR in solid hydrogen, hydrogen in alkali metal-graphite intercalation compounds, lattice anomalies and Grueneisen parameters in high Tc superconducting salts, bio-substances and hydrogen, hydrogen bond net in nucleotide and control of crystalline structure change by hydrogen vapor pressure, ATP and structural change and crystal water of guanosine, spread of protons and electrons in hydrogen bond, anisotropy of loose scattering according to ice rule, high pressure effect and isotope mixed crystal effect of KHS crystals without hydrogen crystal network, state of motion and phase transformation of hydrogen in KDP, and development of hydrogen bond research by neutron scattering. This publication contains the papers and the transparencies presented at the meeting. DOE

BROAD SPECIFICATION FUELS COMBUSTION TECHNOLOGY PROGRAM, PHASE 2 Final Report
R. P. Lohmann, R. A. Jeroszko, and J. B. Kennedy Oct. 1990 235 p
(Contract NAS3-23269)
(NASA-CR-191066; NAS 1.26:191066) Avail: CASI HC A11/MF A03

An experimental evaluation of two advanced technology combustor concepts was conducted to evolve and assess their capability for operation on broadened properties fuels. The concepts were based on the results of Phase 1 of the Broad Specification Fuel Combustor Technology Program which indicated that combustors with variable geometry or staged combustion zones had a flexibility of operation that could facilitate operation on these fuels. Emphasis in defining these concepts included the use of single pipe as opposed to duplex or staged fuels systems to avoid the risk of coking associated with the reduction in thermal stability expected in broadened properties fuels. The first concept was a variable geometry combustor in which the airflow into the primary zone could be altered through valves on the front while the second was an outgrowth of the staged Vorbix combustor, evolved under the NASA/P&W ECCP and EEE programs incorporating simplified fuel and air introduction. The results of the investigation, which involved the use of Experimental Referee Broad Specification (ERBS) fuel, indicated that in the form initially conceived, both of these combustor concepts were deficient in performance relative to many of the program goals for performance emissions. However, variations of both combustors were evaluated that incorporated features to simulate conceptual enhancement to demonstrate the long range potential of the combustor. In both cases, significant improvements relative to the program goals were observed. Author (revised)

THERMOPHYSICAL PROPERTIES OF REFRIGERANT R-134a (1,1,1,2-TETRAFLUOROETHANE)
Mar. 1993 17 p
(ISSN 0141-4062)
(ESDU-93001; ISBN-0-85679-855-X) Avail: ESDU

ESDU 93003 gives equations obtained from a critical evaluation of experimental data in the literature for the variation along the saturation line with temperature, for both the liquid and the vapor, of density, ehthalpy, heat capacity at constant pressure, dynamic viscosity, and thermal conductivity. Results on the saturation line evaluated in SI units using the equations are tabulated at 5K intervals and at 5 C intervals from the melting point to the critical point, or as close to it as possible for some properties. Results for the ideal gas evaluated also in SI units using the equations are tabulated at 5 K and at 5 C intervals from the melting point to 1000 K. In the absence of experimental values, some of these results involve extrapolation and they are indicated in the tables. Conversion factors to facilitate use of the data in British units are included. ESDU

APPLICATION OF THE POSITRON ANNIHILATION TECHNIQUE TO THE STUDY OF VAPOR ABSORPTION PROCESS IN POLYETHYLENE (LDPE) AND IN IMIDE POLYMER (6FDA-TMPD PI) Ph.D. Thesis
V. Sanchez Mendieta 1992 92 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-602737; INIS-mf-13615) Avail: CASI HC A05 (US Sales Only)

It is well known that positron annihilation lifetime (PAL) spectra in polymers have a long-lived component that can be ascribed to ortho-positronium (o-Ps). The lifetime, (tau)(sub 3), is considered to be a measure of the size of the micro-vacancies in which o-Ps is trapped and is annihilated through pick-off annihilation with the rate which depends on the size of the vacancy. Positron lifetime measurements were performed for two different kinds of polymers (low density polyethylene and a polyimide) (6FDA-TMPD) during sorption of various vapors (hexane, cyclohexane, benzene, acrylic acid, methyl acrylate, water, and oxygen). The vapor sorption affected the long-lived component (ortho-positronium component) in a systematic way regardless of the kind of the vapor molecules, i.e. for the polyethylene both the lifetime and the intensity of the long-lived component were enhanced, while for the polyimide they were decreased significantly. These different effects are interpreted in terms of different states of sorbed molecules in rubbery (the polyethylene) and in glassy (the polyimide) polymers. DOE

THERMAL CONDUCTIVITY OF LIQUID ALIPHATIC ALCOHOLS
Mar. 1993 82 p Supersedes ESDU-75024
(ISSN 0141-4062)
(ESDU-93008; ESDU-75024; ISBN-0-85679-860-6) Avail: ESDU

ESDU 93008 gives data for all isomers up to C6, for 6C7 isomers, 4C8 isomers, 2C9 isomers, and for the normal alcohols from C10 to C20. Experimental results drawn from the literature for each compound were fitted with a four term polynomial equation in reduced temperature. The coefficients were also faired with changing molecular structure to ensure the best correlation not only for the individual compounds but also as members of their chemical series. The coefficient correlations also allowed values to be predicted for compounds for which no measured data exist. For these compounds, it was found only one coefficient varied across the families, while the other three remained constant. The equations were used to tabulate thermal conductivity values from the melting point to about 0.9 critical temperature in SI units at 10 K and 10 degree C intervals. The critical point, coefficients and sources of the data are given for each compound. Conversion factors are provided for common British units, the effect of pressure is briefly considered and the likely accuracy of the tabulated values is discussed. ESDU

VAPOUR PRESSURES AND CRITICAL POINTS OF LIQUIDS: ALIPHATIC AND CYCLIC KETONES
Mar. 1993 94 p
(ISSN 0141-4062)
(ESDU-93009; ISBN-0-85679-861-4) Avail: ESDU

ESDU 93009 presents vapor pressure data for all isomers (26 compounds) of aliphatic ketones up to C7, 13 aliphatic ketones between C8 and C15, mesityl and isomesityl oxides, and cyclo-butanone, -pentanone, -hexanone, -heptanone and -octanone. The data were obtained by a critical evaluation of experimental results in the literature correlated by a method that allows the extrapolation of results in the higher pressure ranges into the low pressure region. The method also enabled correlations to be developed for compounds for which only restricted results were available using correlations for compounds for which a wide range of data existed. The Wagner equation was used over the full liquid range from the melting point to the critical point. The coefficients of the equation are given for each compound and three tables of vapor pressure values calculated using them are included: in SI units at 5 K intervals, in mm of mercury or atmospheres at 10 degree C intervals, in lbf/sq in at 20 degree F intervals. A table also gives the saturation temperature at various specified pressures, and indicates the possible uncertainty in the calculated values. The sources of the data for each compound are included. ESDU

ORTHOBARIC DENSITIES AND MOLAR VOLUMES OF LIQUIDS: ALIPHATIC AND CYCLIC KETONES
Mar. 1993 102 p
(ISSN 0141-4062)
(ESDU-93010; ISBN-0-85679-862-2) Avail: ESDU

ESDU 93010 tabulates density and molar volumes for all isomers (26 compounds) of aliphatic ketones up to C7, 13 aliphatic ketones between C8 and Cl5, mesityl and isomesityl oxides, and cyclo-butanone, -pentanone, -hexanone, -heptanone and -octanone. The tables are in units of kg/cu m and cu cm/mol respectively from near the melting point to within a few degrees of the critical point. The temperature interval chosen is varied from 10 K to 1 K to keep the increments in density reasonably small. Although the Rackett equation does not represent the variation of density over the full temperature range so well as the equation used in ESDU 93010 (log reduced density as a polynomial function of reduced temperature), it was used to estimate the critical density. The estimated values were slightly adjusted to give a smooth variation between compounds. The log/polynomial equation was then fitted to the experimental data for density for each compound taken from a wide range of sources in the literature; values established for the coefficients in the equation for each compound are also tabulated. Estimates of the accuracy of the predictions are included, as is a list of the sources of data actually used for each compound. Values at the critical point are provided together with normal boiling and melting points. ESDU

N94-28062 ESDU International Ltd., London (England).
VISCOSITY OF LIQUIDS: HALOGENATED ETHANES
Nov. 1993 65 p
(ISSN 0141-4062)
(ESDU-93012; ISBN-0-85679-864-9) Avail: ESDU

ESDU 93012 tabulates the viscosity of 49 halogenated ethanes at saturation pressure for temperatures from just above the melting point to approximately 0.9 of the critical temperature. Experimental data extracted from the literature were fitted by an equation for the logarithm of dynamic viscosity as a function of reduced temperature. The equation contains four constants and the values determined for them from the correlation are tabulated for each compound. Viscosities are given at 10 K and 10 degree Celsius intervals, together with an assessment of the uncertainty in each value. The sources of the data for each compound are listed, and the critical temperature is given. It is noted that viscosity increases by 1 percent for a pressure increase of 10 bar, and an equation is suggested for calculating the effect of pressure up to 500 bar. ESDU

This report presents results of measurements on low refrigerant concentration mixtures (0, 10, 20, and 30 weight percent) of CFC-12; HCFC's 22, 123, and 124; and HFC's 134a, 32, and 125 with mineral oil, alkylbenzene, and polyolester lubricants. Viscosity, solubility (vapor pressure), and density data are reported for 23 working fluids composed of combinations of these refrigerants and companion lubricants. These data, reduced to engineering form, are presented in form of a Daniel chart and a plot of density versus temperature and composition. Extensive numerical analysis has been performed in order to derive equations which allow two independent variables, temperature and composition, and to provide for corrections in composition due to vapor space volume in the test apparatus; details of these calculations are provided. ORTHOBARIC DENSITIES AND MOLAR VOLUMES OF LIQUIDS: FUSED RING COMPOUNDS
Sep. 1993 66 p
(ISSN 0141-4062)
(ESDU-93029; ISBN-0-85679-882-7) Avail: ESDU

ESDU 93029 tabulates density and molar volume for 30 compounds in units of kg/cu m and cu cm/mol respectively from near the melting point to the critical point (although for some compounds the tables are terminated at about 0.8 of critical temperature). The temperature interval is varied from 10 K to 1 K to keep the increments in density reasonably small. The critical density was calculated using the Rackett and Riedel equations and values of critical pressure and temperature adjusted until the predictions of critical density from the two equations were in good agreement. Experimental data for density for each compound were taken from a wide range of sources in the literature and fitted by an equation for log reduced density as a polynomial function of reduced temperature. Values for the coefficients in the equation are tabulated for each compound together with estimates of the accuracy of the predictions using them and a list of the sources of data used. Values at the critical point are also given together with normal boiling and melting points. Vapor pressure data for all the compounds are given in ESDU 93028. ESDU

Sep. 1993 80 p
(ISSN 0141-4062)
(ESDU-93028; ISBN-0-85679-881-9) Avail: ESDU

ESDU 93028 presents vapor pressure data for 37 compounds. The data were obtained by a critical evaluation of experimental results in the literature. Where the data were less extensive or reliable, it was found possible to develop a correlation using a method that relates the second differential of the Wagner vapor pressure equation to the difference between the ideal gas and the liquid heat capacities. The Wagner equation was used over a temperature range usually from close to the melting point to the critical point, although for some compounds the correlation was stopped at about 0.8 of the critical temperature. The coefficients of the equation are given for each compound and two tables of vapor pressure values calculated using them are included: in SI units at 5 K intervals and in mm of mercury or atmospheres (for the higher values) at 5 C intervals. A table also gives the saturation temperature at various specified pressures and indicates the possible uncertainty in the calculated values. An Antoine equation is given fitting the Wagner equation values between 2 and 200 kPa with an rms deviation of between 0.05 and 0.1 percent. The sources of data for each compound are also listed. Density data for the majority of the compounds are given in ESDU 93029. ESDU

FREON RECOVERY FROM NITROGEN TETROXIDE AND FREON SOLUTIONS Final Report
Robert O. Bucsh Apr. 1993 34 p
(PL-TR-92-3051) Avail: CASI HC A03/MF A01

A reactor was designed, built, and tested to extract N2O4 from a N2O4 in Freon solution. A two step chemistry process was developed, the N2O4 is extracted from the Freon as KNO2 and KNO3 with aqueous KOH. The KNO2 is converted to N2 aud K2SO4 by sulfamic acid. The excess KOH is neutralized with nitric acid to produce an innocuous KNO3 solution. The concentration of N2O4 left in the treated Freon is below the detection limit of the analytical method used. It was discovered that N2O4 reacts with Freon over time to produce halogenated nitroethanes. The reactor has been delivered to the Western Space and Missile Center (WSMC). Author

Materials capable of laser emission in the mid-infrared wavelength range are studied for 3-5 and 4-6 group semiconductors. This study was intended to establish the ways of making thin films out of these materials, construct double heterojunction or multi-quantum well structure to lasers, and to raise the laser operational temperature in this wavelength range. The study found that, in 3-5 group semiconductors, heterojunction joining with flat surfaces can be generated by inserting In(1-y)Al(y)Sb component tapered layers between the InSb substrate and the confinement layers in order to prepare the In(1-x)Ga(x) Sb/In(1-y)Al(y)Sb laser. Ga molecular beams were ionized by two photon excitation, utilizing light resonance absorption. In 4-6 group semiconductors, a new material Pb(1-x-y)Cd(x)Sr(y)S proved to be suitable for lasers. By MBE (Molecular Beam Epitaxy), the technique to control this film thickness in an atom's precision was established, and Pb(1-x-y)Cd(x)Sr(y)S/PbS double heterojunction and multi-quantum well lasers were produced. By employing the Pb(1-x-y)Cd(x)Sr(y)S/PbS double heterojunction, laser emission succeeded at 240 K, the highest operational temperature in this wavelength range. Author (NASDA)

CORROSION RESISTANCE AT WELDED ZONES OF NUCLEAR FUEL REPROCESSING SYSTEM [KAKU NENRYO SAISHORI SOCHI YOSETSUBU NO TAISHOKUSEI NI KANSURU KENKYU]
Harukata Nakamura, Hirosada Irie, Takehiko Watanabe, Kazuo Ei, Susumu Tsukamoto, Yoshiki Muramatsu, Seiji Kuroda, Tetsuo Fujii, and Haruo Baba *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 17-28 In JAPANESE (For primary document see N94-25544 07-26)
Avail: CASI HC A03/MF A04

Research was conducted to improve the corrosion resistance at welded zones of nuclear fuel recycling system made of austenitic stainless steel. The following results were obtained. Crystal granules as fine as those of the basic material were obtained at welded zones by employing the pulse TIG (Tungsten Gas Welding) welding method specially developed to reduce the granule size. The TIG welded zones of austenitic stainless steel with finer crystal granules have far more corrosion resistance than those which did not undergo this process. Welded zones with electron beam treatment proved to have extremely high corrosion resistance. In research on the surface treatment with laser, surface fusion solidification by CO2 laser did not effectively reduce the size of crystal granules, but high speed solidification fusion treatment by laser utilizing the segregation effect contributed much to improve corrosion resistance. However, this high speed treatment caused some cracks in the stainless steel. To obtain some basic knowledge about fusion and solidification, cladding experiments were made on Ti and Ta. Corrosion resistance of valve metals such as Ti and Zr in nitric acid solution with oxidizing ions was evaluated by the AC (Alternation Current) impedance method. Complete corrosion resistance was seen when oxidizing ions were present. In boiling nitric acid, a correlation was noticed between DC (Direct Current) polarization resistance values and corrosion rates calculated by the decrease in weight. Author (NASDA)

INTERACTIONS BETWEEN CORROSION FATIGUE AND STRESS CORROSION CRACK ON STEEL FOR LIGHT WATER REACTORS [KEISUIROYO KINZOKU ZAIRYO NO FUSHOKU HIRO-ORYOKU FUSHHOKUWARE SOGO SAYO NI KANSURU KENKYU]
Norio Nagata, Tadao Ishihara, Shinobu Matsushima, Yasuyuki Katada, Shunji Sato, and Shigeo Ohashi *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 29-42 In JAPANESE (For primary document see N94-25544 07-26)
Avail: CASI HC A03/MF A04

In order to evaluate material safety in the coolant environment, investigation is conducted concerning the interactions between corrosion fatigue and stress corrosion crack as well as environment factors which influence the incidence and crack growth in hot, high pressure water. Rolling alloy steel JIS (Japanese Industrial Standards) SQV2A used for pressure vessels and forging material SFVQ1A served as test samples. In the compound load experiment of fatigue and tension at low strain rate, no notable interactions were recognized which may affect the crack growth rate. It was found that the crack growth rate is proportional to the density of dissolved oxygen, and inversely proportional to the flow rate. The faster the crack growth rate was, the lower the corrosion electric potential was, especially in materials including more sulfur. No distinct correlation was found between the corrosion electric potential and dissolved oxygen. In dissolution study of MnS between cracked fractures, dissolution occurred more easily (at lower temperature) in crevices than on free surfaces. In the fatigue test in hot, high pressure water fatigue life of SQV2A material found more dependency on the strain rate (slower strain rate shortened the fatigue life) than that of SFVQ1A material. Continuing from the first and the second term, creep rupture data sheet on metals for high temperatures was continued targeting for 100,000 hours. Creep strain data sheet for elastic analysis, conceived in the second term was carried out this term. Additionally, research was planned into the Cr group steel, which is increasingly in demand for high temperature equipment, and material sampling and testing commenced accordingly. In 1986, the creep data sheet (B Version) was published for the first time, including the creep rupture data exceeding final target of 100,000 hours. Since then, B versions were published on 12 different materials this term. There has been much research using the data from creep data sheets and test samples, including creep strain characteristics, stress relaxation characteristics, creep rupture characteristics and life estimate, with substantial results. In the creep test technology aiming for highly reliable data, deterioration factors of thermocouples were investigated. The results from creep data sheets and related research contributed to improvement in strength reliability of metals at high temperatures. Author (NASDA)

R AND D FOR CREATION, MEASUREMENT, APPLICATION OF ULTRA-HIGH VACUUM [GOKUKOSHINKU NO HASSEI, KEISOKU, RIYO GIJUTSU NO KAIHATSU NI KANSURU KENKYU] **c31**

Kazuhiro Yoshihara, Masahiro Tosa, and Michiko Yoshitake *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 65-74 In JAPANESE (For primary document see N94-25544 07-26)
Avail: CASI HC A02/MF A04

Stainless steel has widely been used as material for vacuum vessels. Attempts were made, utilizing surface deposition phenomenon, to make the stainless steel surface absorbent of gas. First, BN and SUS304 steel were mixed and put on a steel board. This BN/SUS304 steel mixture proved to be effective as coating material for the surfaces of super high vacuum vessels, because low gas absorbing BN can easily be coated at low temperature. In the next experiment of BN treatment with magnetron spatter electrodes, BN/SUS304 steel mixture films were uniformly evaporated and coated inside a compact vacuum vessel. Measurement by the throughput method revealed that the gas release rate in this compact vacuum vessel was smaller by one digit than that in a vessel without BN coating. Thus, a vacuum chamber was easily made into a super high vacuum chamber with high performance. In the third experiment, Ti separation films with getter functions for O2 and CO2 were obtained by evaporating Nb films on Ti and heating it in vacuum at approximately 800 K. These films function as getters at 473 K and do not require as high a temperature as sublimation pumps. It was thus proved that it is possible to use the material separation Ti film/Nb film/ Ti in getter pumps for released gas caused by filaments or heat from the filaments. Author (NASDA)

KNOWLEDGE BASE SYSTEMS FOR CHEMICAL COMPOUNDS DESIGNING SUPPORT [KAGAKU BUSSHITSU SEKKEI TO SHIEN NO TAME NO CHIHSIKI BESU SHISUTEMU NI KANSURU KENKYU] **c82**

Michio Yamazaki, Kenichi Hoshimoto, Toshihiro Yamagata, Katsumi Ono, Hidehiro Onodera, Hiroshi Harada, and Tadaharu Yokokawa *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 75-86 In JAPANESE (For primary document see N94-25544 07-26)
Avail: CASI HC A03/MF A04

An attempt was made to construct a dialog type alloy design system and conception support knowledge base system utilizing treatises as sources of knowledge. This was intended to investigate intelligence base systems that would contribute to the development in steel material. The alloy design program presently in use is incorporated with a procedure type program, and it is unlikely that intelligence base be practically applied in our development because creating variations will be a totally different research requiring tremendous amount of work. Meanwhile, conception support systems which provide information wanted by researchers will be very useful because the present world is full of research informations. Under these circumstances, a dialog type knowledge search system with natural language was prepared. It revealed that a system incorporating a personal computer could not be put into practical use due to memory and processing speed restrictions, however, some basic functions were confirmed. More practical search system and intelligence compiling tools were developed employing an engineering work station and the expert shell. Although these systems are still prototypes, they are expected to serve as effective development support tools by enriching the knowledge contents. Author (NASDA)

HYDROGEN TRAPPING WITH Pd COATED ALLOY FILMS [PD HIFUKU SHITA GOKINMAKU NO SUISO NO TORAPPINGU GENSHO NI KANSURU KENKYU]

Muneyuki Amano, Chikashi Nishimura, and Masao Komaki *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 87-92 In JAPANESE (For primary document see N94-25544 07-26)
Avail: CASI HC A02/MF A04

Alloy films subject to oxidization must be coated with a material, such as Pd, which is not easily oxidized and has high permeability before they can be used as hydrogen separation films. Research into hydrogen trapping with Pd-coated V-15 at percent Ni alloy films at 373-673 K was conducted. The research focused on film surfaces before Pd coating and impure objects affecting hydrogen permeability, and measures to eliminate this phenomenon are investigated. The following results are obtained: (1) surface layers generated by machine polishing cause notable H2 trapping at approximately 473 K or less; (2) oxidized films remained between Pd films and alloy films, and caused hydrogen trapping at low temperatures; (3) impurities, especially oxygen atoms, which intruded into alloy films reduce hydrogen permeability significantly at 673 K, but this can be prevented by adding an adequate amount of deoxidizer such as Y, Ti and Zr; (4) deoxidation was not effective in repressing hydrogen trapping on V-15 at percent Ni alloy at approximately 473 K or less. This was considered to be influenced by their surfaces; (5) it was concluded that a solid solution O effectively reduces the valid area for hydrogen permeation; and (6) the hydrogen diffusion coefficient in V-15 at percent Ni alloy was bigger than that in Pd, but was much smaller than that in V. BASIC RESEARCH ON LEVITATION FUSING/SOLIDIFICATION TECHNOLOGY [FUYO YOKAI GYOKO GIJUTSU NI KANSURU KISOTEKI KENKYU]

Kazuyuki Sakuraya, Akira Fukuzawa, Toshiaki Watanabe, Sadao Furuyama, Satoshi Iwasaki, and Tatsuro Mitsui *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 93-96 In JAPANESE (For primary document see N94-25544 07-26)
Avail: CASI HC A01/MF A04

Research was made on levitation force toward metal balls in cold crucibles to obtain basic data for the most suitable levitation fuse conditions. Cold crucibles with different slit width and number of slits were prepared. The number of slits on the crucibles varied from one to 24. Different power frequencies varying from 3 to 10 kHz were applied. In two cases with coil positions allowing maximum levitation force, levitation force increased as the number of slits did, although it was not proportional. In these two cases, levitation force increased as the slit width increased as well. However, in the third case where the coil position did not allow the maximum levitation force, the results were opposite from the above cases. It was thus concluded that the coil positions and shapes (windings and height) are important factors to be considered for levitation force as well as the number of slits, slit width, and power frequencies.

INNER FIBER OBSERVATION FOR METAL MATRIX COMPOSITES UNDER THE STRESS LOAD CONDITION UTILIZING SYNCHROTRON ORBITAL RADIATION (SR) BY X-RAY CT [SHINKUROTORON HOSHAKO (SR) O RIYO SHITA X SEN CT BU YORU ORYOKU FUKA JOTAI NI OKERU FUKUGO ZAIRYO NO NA!BU KANSATSY]

Chitoshi Masuda, Yoshihisa Tanaka, P. Mahajan, Katsuhisa Usami (Hitachi Ltd., Tokyo, Japan.), and Tatsumi Hirano (Hitachi Ltd., Tokyo, Japan.) *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 97-106 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A02/MF A04

Observations were made of inner fiber damage in metal matrix composites (MMC) by using stress load equipment in concert with X-ray CT (Computer Tomography) equipment. A layer of test samples was prepared from long fiber strengthened MMC's, and a stress load was applied to observe the breaking process. The X-ray images of SiC (C)/C/A6N01 material and B (W)/A6N01 material after the stress load process showed different break structures. Inner fiber ruptures and strengthened fiber slippings that were observed should contribute useful information to clarify the relationship between the surface and dynamic characteristics. By observing particle dispersion strengthened MCC's by means of X-ray CT, it was found that the accompanying void generation, up to the maximum tension force, remained almost unchanged, like that with no load; although, the void size increased as the load increased. Voids were also generated just before the sample failed. In conclusion, it is possible to measure and analyze the damage in MMC's due to strain load tension processes. It is also possible to gather data on broken fiber length as it relates to rupture characteristics. It was also confirmed that the equipment developed in this research was effective. Author (NASDA)

OBSERVATION ON METAL SURFACE IN AQUEOUS SOLUTION USING AN ELECTROCHEMICAL SCANNING TUNNELING MICROSCOPE (STM) [SOSAGATA TONNERU KENBIKYO NI YORU KINZOKU/SUIYOEKI KAIMEN NO SOKUTEI NI KANSURU KENKYU]

Saburo Matsuoka, Hiroyuki Masuda, and Nobuo Nagashima *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 107-114 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A02/MF A04

A Scanning Tunneling Microscope (STM) which can function in an aqueous solution was constructed to observe damage at high magnification including corrosion, corrosion fatigue, and stress corrosion generated in aqueous solution. The surfaces of gold, pure iron thin film, low alloy SNCM439, and austenitic stainless steel SUS304 were observed in the anode and cathode areas in an aqueous solution of NaCl (1 percent) and HNO3 (0.1 percent). By using a coated probe and a bipotentiostat, which allows the electric potentials of the probe and test samples to be set separately, the STM observed large areas ranging from the cathode to the anode in high magnification mode. The maximum possible magnification was 70 nm in X-Y scan areas, equivalent to 200 metal atoms. Transitional surface changes by corrosive dissolution could be observed, and thus, corrosion could be measured quantitatively by subtracting an STM image from another. Author (NASDA)

FUNDAMENTAL STUDY ON MONITORING TECHNOLOGY ON LOCAL SURFACE DAMAGES [HYOMEN KYOKUBU SONSHO NO MONITARINGU GIJUTSU NI KANSURU KISOTEKI KENNYU]

Yasuyuki Katada and Shunji Sato *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 115-122 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A02/MF A04

Research was conducted to evaluate the surface corrosion/damage of steel used for pressure vessels in hot, high pressure water environments. The research simulated the environment of light water reactor coolants. The research was intended to establish electrochemical measurement technology in the above environment and to clarify/resolve the cracking mechanism in this environment by applying the AC (Alternating Current) impedance method to local damage and checking the possibility of this method in the future. Mn-Mo-Ni alloy steel and Wedge Opening Loading (WOL) type test samples were used as test samples, and polarization and AC impedance were measured. The following results were obtained: (1) electrochemical measurement systems were established including the AC impedance method in the environment of hot, high pressure water; and (2) the AC impedance method proved to be applicable for local damage evaluation. This was concluded by the clear characteristic differences seen between the WOL type test samples with cracks and those without cracks after impedance measurement. Author (NASDA)

STUDY ON PHASE TRANSFORMATION DUE TO DEFORMATION IN FERROMAGNETIC FIELDS AT CRYOGENIC CONDITION [GOKUTEION, KYOJIBAKA HENKEI NI YOUR SOHENTAI NI KANSURU KEKNKYU]

Kotobu Nagai, Toshio Ogata, Toshimi Yuri, Osamu Umezawa, and Keisuke Ishikawa *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 123-129 In JAPANESE Prepared in cooperation with Tokyo Univ., Japan; and Toshiba Corp., Kanagawa, Japan Sponsored by Science and Technology Agency, Tokyo, Japan (For primary document see N94-25544 07-26)

Avail: CASI HC A02/MF A04

Deformation restoration tools and phase transformation quantization methods were studied to establish the relationship between deformation and phase transformation. The purpose of this study was the quantitative evaluation of effects on the phase transformation of metastable austenitic stainless steel caused by deformation and ferromagnetic fields. Deformation load equipment was constructed to apply a load of two tons in maximum to a small deformation tensile bar. This was intended to simulate magnets with rather large gauges of 50 mm inside diameter. By utilizing the paramagnetism of the austenitic phase and the ferromagnetism of the bcc (body centered cubic) martensitic phase formed with the phase transformation, a quantization method with high precision was developed by magnetization curves in the liquid helium temperature. Next, the relationship between deformation and phase transformation amount was investigated on 300 system austenitic stainless steel. The bcc martensitic phase was not formed on 304L or 316LN steel by refrigeration down to 4 K. The formed 316LN steel remained stable in shape until its tension fracture at room temperature, while some bcc martensitic phase was formed on 304L steel. At 77 K or less, both samples transformed due to deformation, and it was aggravated by the effect of magnetic fields. Author (NASDA)

Avail: CASI HC A02/MF A04

Joint research was carried out with research institutes in France on the development and application of ferromagnetic field technologies. In order to clarify how the specific magnetic characteristics such as Cu spinning and Gd moment contribute to conductivity, Gd(2-x)Ce(x)CuO4 was used for a systematic study of electrical and magnetic field resistance against Ce concentration. Magnetism was precisely measured to obtain magnetic characteristics including magnetic transition and its relationship with conduction phenomena. The Gd group is quite suitable for the study of correlation between the two dimensional conduction and magnetism because its magnetic characteristics systematically change against Ce concentration. Current-magnetic effects of InSb were investigated in ferromagnetic fields at extremely low temperatures. At the quantum limit, it was clarified that the diagonal component becomes zero while the electroconductivity tensor stays constant. Author (NASDA)

STUDY ON REACTIONS BETWEEN MOLTEN METAL AND OXIDE BY MAGNETIC FLOTATION DISSOLUTION METHOD [JIKI FUJO YOKAIHO NI YORU YOYU KINZOKU-SANKABUTSU KAN HANNO NI KANSURU KENKYU]

Akira Fukuzawa, Kazuyuki Sakuraya, Toshiaki Watanabe, and Yasumitsu Fukuzawa *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 137-139 In JAPANESE Sponsored by Science and Technology Agency, Tokyo, Japan (For primary document see N94-25544 07-26)

Avail: CASI HC A01/MF A04

The cold crucible type non-contacting dissolution method was investigated as a means to dissolve active metals or metals with high melting points and to prepare materials with high purity. The non-contacting electroslag refining method was investigated. This was intended to provide reaction and purifying functions to the cold crucible type non-contacting dissolution equipment which is now under development. While it is difficult to process slags with low surface tension without a vessel, it was assumed that a thin slag coating on metal surfacesmight be achieved. To investigate this assumption, experiments were made on Si containing iron in a cold crucible reactor with power frequency of 200 kHz. SiO2 films were successfully formed on the surfaces. An investigation was also made into oxide solubility with power in 4 MHz. Author (NASDA)

STUDY ON FERROMAGNETIC FIELD MAGNET USING STRONG AND HIGHLY CONDUCTIVE MATERIAL [KOKYODO, KODODEN ZAIRYO O MOCHIITA KYOJIKAI MAGUNETTO NI KANSURU KENKYU]

Hiroshi Maeda, Kiyoshi Inoue, Hitoshi Wada, Yoshiaki Tanaka, Kikuo Ito, Takao Takeuchi, Toshihisa Asano, Yoshikazu Sakai, Tsukasa Kiyoshi, and Yukikazu Iwasa *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 141-143 In JAPANESE Prepared in cooperation with MIT, Cambridge Sponsored by Science and Technology Agency, Tokyo, Japan (For primary document see N94-25544 07-26)

Avail: CASI HC A01/MF A04

Strong, highly conductive materials which can be used for ferromagenetic fields were developed and evaluated jointly with the Francis Bitter National Magnet Laboratory in the United States. The design and preparation of such materials were also studied. In this research, Cu-Nb and Cu-Ag alloy filaments were developed, and the pulse magnet was considered as a constant conductive magnet with ferromagnetic fields. Several problems were found with Cu-Nb alloy. On the other hand, Cu-Ag showed some outstanding results. The conductivity and strength of the Cu-Ag alloy were improved during the annealing process. Additionally, high mechanical strength was obtained with intermediate annealing. However, measurement showed that the increase in the resistance of Cu-Ag alloy in ferromagnetic fields resembled that of other Cu group alloys; that is, resistance increase did not reach saturation in ferromagnetic fields. This fact requires some investigation into magnet design. It was also found that the resistance at extremely low temperatures decreased to approximately 30 percent of that at room temperature. Goldfarb *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 145-148 In JAPANESE Prepared in cooperation with National Inst. of Standards and Technology, Gaithersburg, MD Sponsored by Science and Technology Agency, Tokyo, Japan (For primary document see N94-25544 07-26)

Avail: CASI HC A01/MF A04

Research was conducted jointly with the National Institute of Standards and Technology (USA) regarding test and evaluation methods for superconductors. The main themes were as follows: (1) measurement of the critical current of oxidized superconductors; (2) measurement of alternating current loss in advanced metal superconductors; and (3) development of software programs for measurement automation. For the measurement of the critical current of oxidized superconductors, the pulse current method was improved in order to have the accuracy necessary to deal with the problem of heat generation at electrodes. As a result of the technique developed, highly accurate measurement of critical current was attained even at silver pasted electrodes. In the next experiments, the transverse stress of Nb3Al wires was measured. Attention was paid because it is expected to be the next superconductor to be used in the future after Nb3Sn. It was clarified that the critical current degradation due to axial and transverse stress in Nb3Al wires is extremely smaller than that in Nb3Sn wires. Also, the values obtained in the experiment suggested that there was little difference between axial and transverse stress dependency in the critical current of Nb3Al superconductive filaments. COMBUSTION SYNTHESIS METHOD [NENSHO GOSEIHO NI KANSURU KENKYU] **c25**

Yoshinari Kaieda, Minoru Otaguchi, Nobutaka Oguro, and Z. A. Munir *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 149-151 In JAPANESE Prepared in cooperation with California Univ., Davis (For primary document see N94-25544 07-26)

Avail: CASI HC A01/MF A04

Joint research was performed regarding the creation of chemical compound material by combustion synthesis as well as evaluation of the chemical compound material created. The basic mechanism of combustion synthesis was clarified using TiN and rarefied nitrogen gas. In this research, heat generation was reduced and the temperature lowered preventing overall dissolution and promoting nitrogen gas intrusion. Thus, improving the TiN conversion rate was investigated. When rarefied gas was used for nitrogen material at combustion synthesis, the slower the reaction spread speed was the more TiN was generated. This reverse dependency between TiN conversion rate and the reaction spread speed is relevant to the fact that violent reactions spread avoiding powder clusters. This prevents nitrogen gas from intruding inside. Mild reactions spread slowly, supplying sufficient nitrogen gas to the areas of reaction, thus increasing the TiN conversion rate. This rate improves in materials which contain the end product, TiN, from the beginning. However, if the TiN percentage in a material exceeds 50 percent, combustion synthesis stops. Author (NASDA)

DEVELOPMENT OF SO(x) AND NO(x) SOLID ELECTROLYTE SENSORS [SO(X), NO(X) KOTAI DENKAISHITSU SENSA NO KAIHATSU NI KANSURU KENKYU] **c35**

Hiroaki Nakamura, Mikihiko Kobayashi, Akira Kasahara, Yoichi Ogawa, Hiroaki Isago, and Isao Morinaka *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 153-164 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A03/MF A04

Compounds suitable for solid electrolyte sensors were sought, and the composing methods were investigated in order to improve measurement of SO(x) and NO(x). Various compounds were dissolved, and test samples were made amorphous by quick cooling to compose each group of M2O-B2O3-M2SO4 (M = Li, K, Na) as solid electrolytes for SO(x). The samples composed by this method showed electric conductivity of 10(exp -3) S/cm or more, which meant that the samples could be solid electrolytes. Polarization measurement indicated that the samples were ion conductors. K2O-B2O3-K2SO4 was used as a solid electrolyte for a low density sensor to measure electromotive force. The actual electromotive force values and theoretical values were almost the same at 0.5 ppm or more. When the electromotive force was measured using Li2O-B2O3-Li2SO4 for a high density sensor, the actual values and theoretical values coincided at 10-1000 ppm. The electromotive force responsiveness of solid electrolyte sensors to the changes in gas density was approximately 1 minute, proving that Li2O-B2O3-Li2SO4 is available as a solid electrolyte for sensors. Electric conductivity rose in the composed sample of Ca(NO3)2-NaNO3 and CsNO3-NaNO3 composed by pressurized baking. Both samples showed high electric conductivity, revealing possible applications in sensors. Author (NASDA)

STUDY ON SYNTHESIS AND CHARACTERISTICS OF INTERMETALLIC COMPOUND WITH STRONG ELECTRON CORRELATION [TSUYOI DENSHI SOKAN O YUSURU KINZOKUKAN KAGOBUTSU NO GOSEI TO BUSSEI NI KANSURU KENKYU]

Haruyoshi Aoki, Shinya Uji, Masanori Yata, and Keikichi Nakamura *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 165-172 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A02/MF A04

Research was made on electronic structures of intermetallic compounds containing Ce and U with strong electron correlation. At the same time, thin films were prepared from such compounds to investigate the characteristic changes and new phenomena deriving from pseudo-binary structures. Epitaxy thin films of CeSi2 and CeSb were synthesized by MBE (Molecular Beam Epitaxy). CeSi2 (001) single crystal thin films were composed by evaporating Ce on Si (001) surfaces kept at 1000 C. The galvanomagnetic characteristics observed in thick films of 10 nm or more were the same as those of bulk single crystals. The thinner the films were, the more they were affected by magnetic diffusion for electrical conductivity. CeSb (100) single crystal films were composed by simultaneous evaporation of Ce and Sb on sapphire (0001) surfaces. The same electric conductivity characteristics as those in bulk single crystals were obtained on thick films. The films, however, were quite unstable in the air, and measurement of galvanomagnetic characteristics was not possible. Electronic structures of CeSb and UGe2 were studied by de Haas-Van Alphem (dHvA) effects, and a new high frequency dHvA branch was found for CeSb, which was closely related to important issues on electron structures.

STUDY ON COMPUTERIZED EXPERIMENT OF AMORPHOUS TRANSFORMATION PROCESS BY SOLID PHASE REACTION [KOSO HANNO NI YORU AMORUFASU SEISEI KATEI NO KEISANKI JIKKEN NI KANSURU KENKYU] c76

Katsuyuki Kusunoki, Masato Enomoto, and Tamio Oguchi *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 173-185 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A03/MF A04

Recently, attention has been shifted from the traditional liquid quick cooling to amorphous alloy composition by solid phase reaction. Computer simulation at the atomic level was conducted to clarify the transformation of stable crystal phase to metastable amorphous phase. Molecular dynamics of Leonard-Jones type interatomic potential was employed to simulate the annealing of single crystals and diffusion couples as well as tension of single crystals, and changes in structure were studied. Crystals do not become amorphous in groups containing only simple substances and atomic holes. It requires alloy groups or processes which generate a large amount of negative excess volume to make crystal amorphous by solid phase reaction regardless of the amount of mixed enthalpy. For crystals to become amorphous, atomic couples in different sizes must occur at random to break the crystal regularity.

STUDY ON ALLOY FILMS FOR HYDROGEN SEPARATION [SUISO BUNRIYO GOKINMAKU NI KANSURU KENKYU]

Muneyuki Amano, Chikashi Nishimura, and Masao Komaki *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 187-193 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A02/MF A04

Hydrogen permeability was studied on Pd coated V-Ni alloy films and V-Mo alloy films at 373-673 K. This revealed that an appropriate composition of Ni and Mo will provide potential materials for hydrogen permeation films at temperatures as low as 473 K. The appropriate percentages of Ni or Mo with little hydrogen embrittlement was approximately 15 at percentage and 30 at percentage. With these percentages, both alloy films showed better hydrogen permeability than Pd, and no cracks were formed. Hydrogen permeation of V-Ni and V-Mo alloy films showed a small correlation to temperature. This was because the hydrogen solid solution ratio increases in the same proportion as the hydrogen diffusion coefficient falls with the decrease in temperature. Ductility deteriorates if diffraction phases are present in V-Ni radical alloys. In the tension test of V-15 at percentage Ni alloys, diffracted test samples which went through the melting process did not show much flexibility, whereas the flexibility of the one without diffraction was greater by a significant percentage. Twin deformation and slipping deformation were detected on those samples. The hydrogen solid solution rate was faster at V-Mo alloy film surfaces than at V-Ni alloy film surfaces.

Avail: CASI HC A03/MF A04

The mechanisms of high strength and toughness of titanium alloys were investigated to further improve these properties. The research details were: (1) enhancement of precipitation hardening titanium alloys; (2) enhancement of titanium alloys by rapid solidification powder metallurgy; and (3) quality improvement of joint parts. Micro-dispersion proved to mitigate degradation in fatigue characteristics. Ductility of age hardening materials showed dependency on grain diameters, although strength of these materials did not. Toughness did not depend on crystal grains, but it depended only on strength. Fine two phase texture was obtained with high fatigue strength when PREP (Plasma Rotating Electrode Process) was applied to regular alpha-beta type titanium alloys. The HIP (Hot Isotactic Pressing) process on electron beam welded zones improved the fatigue strength of welded zones. Diffusion welding was studied on Ti-15V-3Cr-3Sn-3A1 (15-3) alloys and Ti-6A1-4V (6-4) alloys. Diffusion junction was easy with 6-4 alloys, but was difficult with 15-3 alloys.

STUDY ON IMPROVEMENTS IN FRETTING FATIGUE CHARACTERISTICS OF HIGH STRENGTH STRUCTURAL MEMBER [KOKYODO KOZO ZAIRYO NO FURETTINGU HIRO TOKUSEI NOJO NI KANSURU KANKYU]

Masae Sumida, Kozo Nakazawa, Ryuichi Hamano, Norio Maruyama, Yoshikuni Kawabe, Satoshi Nishijima, Tetsuo Fujii, and Kazuo Saito *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 207-218 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A03/MF A04

Pad-pressure effects on the fretting fatigue lives of high tension steel and Ti-6A1-4V alloy were investigated. It was clarified that fairly small pressure would minimize the fatigue lives. This is considered to be caused by the centralization of friction and pressure to small contact surfaces. Research was made regarding how cathode anti-corrosion modification affects on fretting fatigue behavior of high tension steel in sea water. Fretting fatigue strength under natural corrosion in sea water deteriorated remarkably compared with that in the air. However, the cathode anti-corrosion modification improved the fretting fatigue strength in sea water and made it higher than that in the air. Environmental influence on fretting fatigue behavior of Ti-6A1-4A alloy was also investigated. The fretting fatigue strength in artificial sea water is generally lower than that in the air. The fretting fatigue strength in LiCl-CH3OH was approximately twice as strong as regular fretting fatigue strength. The corrosion fatigue behavior of high strength steel in sea water was researched. Thin films were coated on the steel surfaces by magnetron spattering and ion mixing. The cohesion of the films effectively improved by the two methods together, preventing the fatigue life from deteriorating due to hydrogen embrittlement.

STUDY ON KNOWLEDGE EXTRACTION AND SYSTEMATIZATION FOR MATERIAL DESIGN [ZAIRYO SEKKEI NO TAME NO CHISHIKI NO CHUSHUTSU TO TAIKEIKA NI KANSURU KENKYU] c82
Kenichi Hoshimoto, Yutaka Kurihara, Akimitsu Miyazaki, Ryuichi Kaneko, Tadaharu Yokokawa, Shuichi Iwata, and Mitsutane Fujita *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 219-230 In JAPANESE (For primary document see N94-25544 07-26)
Avail: CASI HC A03/MF A04

Investigation was conducted on knowledge extraction from published data as well as from visual information which is difficult to computerize, and filing of comprehensive material information which includes images and graphics. Functional inspection was studied for image data processing. Similarities in microscopic photographs of alloy texture were studied by both professionals and non-professionals, and their results were analyzed statistically by multi-dimensional scaling. Alloy texture was expressed roughly in three factors: crystal shapes, anisotropy, and fineness. Quantization of texture characteristics expresses the relationship between texture characteristics and characteristic values regressively and clearly. Next, data collection and data base development regarding binary alloy phase were researched, and software programs were developed accordingly. The image was quantized with an image scanner, and was classified into nodes, lines, and domains to be expressed in a graphic table. Search function was facilitated by search user interface which did not require specific languages for data search on the data base. Author (NASDA)

Bis(tetra t-butylphthalocyaninato) praseodymium (3) and Pr(sup t)Pc2 (Pr = praseodymium, Pc = phthalocianine) were composed as a mixture of multiple isomers by heating a mixture of 4-t-butyl phthalonitrile and praseodymium acetate at 300 C. Bis(tetra t-butylphthalocyaninato) praseodymium (3) has a bulky t-butyl group as a side chain group. Compared to LnPc2 (Ln = lanthanidic ion) which does not have substituents, Pr(sup t)Pc2 proved to have 100-1000 times higher solvency for organic solvents. Pr(sup t)Pc2 showed ESR (Electron Spin Resonance) signals specific to unpaired pi electrons and was radical in toluene solution. The similarity in the electron absorption spectra between Pr(sup t)Pc2 and PrPc2 suggested that PrPc2 was also radical. The electron absorption spectra of LnPc2 were blue in solvents with large donors and green in solvents with small donors, indicating clear solvent dependency. This solvent dependency of Pr(sup t)Pc2 electron absorption spectra is similar to that shown in Ln complexes with large atomic numbers rather than that in LnPc2 complexes with small atomic numbers. Thus, t-butyl radicals are considered to contribute to the stabilization of unpaired pi electrons. Pr(sup t)Pc2 evaporation thin films dipped in electrolytic solution showed different cyclic voltamogram depending on the types and density of electrolytes. Oxidation waves control the diffusion rate of electrolytes in solution, and their potential is linearly dependent to the logarithm of the density of electrolytes. These oxidation waves are also influenced by factors other than electron transfer reactions. Author (NASDA)

Avail: CASI HC A03/MF A04

Research was conducted into different combinations of film coating (both metal and ceramics) on metals. The purpose was to obtain basic knowledge for technology to develop new materials by investigating the surface properties and structures. For ceramic thin films, various types of stainless steel were heated and the surface segregation rate of sulfur was measured. Next, Al2O3 was coated onto the same types of steel and adherence was studied after repeated heating. The result showed that materials containing sulfur which segregated fast had less adherence. Sulfur segregation and Al2O3 exfoliation were both retarded on steels containing Rare Earth Metals (REM). In short, sulfur segregates at surfaces, retarding adherence and promoting exfoliation, whereas REM suppresses surface segregation and exfoliation by trapping sulfur in steels as sulfate. Yttria dispersion was also effective for segregation/exfoliation retarding. For metallic thin films, diffusion of substrate elements on film surfaces was observed by applying low temperature heat so that bulk diffusion could be ignored. Combinations of two elements out of niobium, titanium, and copper were studied. On both samples with titanium as substrates, titanium diffused and condensed on film surfaces. These condensed layers of substrate elements were reproduced even after they were removed by spattering. Author (NASDA)

This research was intended to clarify the mechanism of improving material properties, superconductivity, magnetic characteristics, and atom coupling relevant to electron structures through structural and composition controls by ion beams. Nitrogen ions were implanted to orientation (001) steel thin films at low (10 to 30 K) and room (300 K) temperatures to synthesize nonequilibrium nitride Fe16N2. Different alpha solid solutions or alpha' martensite with different lattice constants were composed at different temperatures. That is, with implantation at room temperature, mainly thermodynamically stable alpha' martensite was obtained. At low temperature implantation, however, nitrogen solid solution of alpha Fe seemed to have been composed as a nonequilibrium phase. Fe16N2 phase was generated after the nitrogen implanted sample was annealed at 423 K for an hour. The diffraction positions of Fe16N2 (002) and (004) were nearly of ideal values at low temperature implantation, and half values were also smaller. At room temperature implantation, alpha' martensite was generated with its c axis vertical to the film surface. Because this phase was stable at high temperature, it was considered to have little driving force for transformation to Fe16N2. Author (NASDA)

By utilizing the solidification process of metal alloys, investigation was made focusing on the following four items with the purposes of producing materials with one directional solidification texture and developing new structured materials. Moldless upward continuous casting: Al-Cu and Al-Si alloy rods with a wide range of freezing points were produced. The crystals of these rods were completely in one direction lengthwise. It was also clarified that pure aluminum rods with various surface shapes could be produced by refractory molding tools. Composite material production by centrifugal casting: Research was conducted to improve wear resistance

and heat dilatation at specific areas of materials by controlling the distribution of the primary Si crystals resulting from centrifugal segregation. The primary Si crystals tend to segregate around the outer circumference of test samples due to centrifugal force. This segregated distribution changes the material properties. Supersonic oscillation application to melting metals: Two methods were investigated to apply supersonic oscillation to melting metals. One was to transmit oscillation by melting metals, and the other to use Al coated film steel horns. Both methods were effective in preventing steel loss from melting steels and grain refinement of solidified texture. Fundamental studies of materials with one direction solidification: It was confirmed that the dendrite became coarse when the solidification rate and solute density were lowered while the temperature was kept constant.

STUDY ON SOLIDIFICATION OF NON-HOMOGENEOUS MELTING/SOLIDIFICATION MATERIALS [FUKINSHITSU YOKAI GYOKOZAI NO GYOKO NI KANSURU KENKYU]

Goro Omori, Osamu Nakano, Tatsuro Mitsui, Hiroo Suge, Nobuo Sakuma, and Kazumasa Togano *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 269-273 In JAPANESE (For primary document see N94-25544 07-26)
Avail: CASI HC A01/MF A04

An attempt was made to produce homogeneous cast lumpby quick solidification from a uniform liquid state. Al-Pb alloys were used for this experiment, and fundamental data were obtained along with property evaluation. The purpose is the production of homogeneous cast lumps of monotectic alloys with big differences in melting points, specific gravities, and little solubility limits with each other. First, Al-Pb alloys up to 30 mass percent on the excess monotectic side were prepared as an amount for Pb in order to obtain fundamental data for alloy production. The factor influencing the texture homogenization was considered to be the cooling rate at two liquid phase separation areas, and Pb diffusion conditions in Al base were studied with the correlation between the cooling rate and textures. At rapid solidification, the cooling rate at two liquid phase separation areas became slower as the alloy mass and Pb density increased. The cooling rate much influenced the solidified textures, and faster cooling rates caused fine, uniform Pb grain diffusion. ZnCl2 and SnCl2 were effective as fusing agents for hot Pb galvanizing. Among various plating methods, excellent wetness and coherency are obtained with the method in which a fusing agent is applied to Al-Pb alloy base and it is solidified by cooling, and then melting Pb is dripped. STUDY ON INTERFACIAL REACTION ANALYSIS AT INTERFACIAL JOINING [KAIMEN SETSUGO NI OKERU KAIMENSO HANNO NO KAISEKI NI KANSURU KENKYU]

Ken Sasabe and Sadao Fukushima *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 275-285 In JAPANESE (For primary document see N94-25544 07-26)
Avail: CASI HC A03/MF A04

Two items were investigated in this research: (1) interfacial coherency by reactions between the solid phase and liquid phase; and (2) interfacial reactions at interfacial coherency by reactions between the solid phase and liquid phase. Compositions of the interface between the solid Cu and the liquid Sn-Pb alloy were studied, and the interface structures of wet ends were assessed. Then, the extended wet work of the Sn-Pb alloy on the Cu board was roughly estimated based on the earlier assessment. The estimated extended wet work was quite similar to the wet behaviors which had been known traditionally. Several types of amorphous alloy coatings were joined with the purpose of developing a welding method without depriving characteristics of amorphous metals obtained by rapid cooling. The resistance spot welding revealed that Co base alloy coating produces joints with good quality, and that it has a potential for practical application. It was assumed that spot welding by laser beams could also be performed on Co base alloy coatings. There remains some joining problems such as contact heat resistance between electrodes and parent metals, quantization of the effects for welding by the overheat of melting metals, and rough coating surfaces. STUDY ON FILM GENERATION PHENOMENA BY PARTICLE DEPOSITION [RYUSHI DEPOJISHON NI YORU HIMAKU KEISEI GENSHO NI KANSURU KANSYU]

Seiji Kuroda, Takeshi Fukushima, Shigeru Kitahara, and Dai Maruo *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 287-298 In JAPANESE (For primary document see N94-25544 07-26)
Avail: CASI HC A03/MF A04

Film generation phenomena were investigated focusing on the plasma spray method, one of the particle deposition methods in which films are created by depositing powdery particles. In the plasma spray method, powders of various materials fused by hot and high speed plasma jets become high speed flying powders and hit main substrates. Research was performed on the cooling speed of fusing particles which hit solid surfaces and spread. Heat transfer coefficients between stacked particles were assessed by the heat conduction rate in the direction of film thickness. The cooling rates calculated from those values show that they could be 10(exp 6) K/s or more. Next, quick cooling stresses of various materials were determined by measuring the curvature of the main board during film generation in order to conduct systematic investigation on the dependency of stresses on the temperature of the main board. The quick cooling stress is a very important factor because it affects the cohesiveness of the films and it can also cause deformation. The cooling stresses of Al and Ni are between 30 and 80 MPa at 373 K, and the stresses deteriorate as the temperature rises. Mo shows similar cooling stress values. In other words, the quick cooling stresses of high strength alloys at high temperature are around 100 MPa, whereas those of ceramics are only about 10 MPa. It is considered that quick cooling stresses are determined by stress mitigating mechanisms such as creeps, plastic deformation, and microcracks. Author (NASDA)

Research was performed on the influence of parameters on the ion intensity, quantization of small amount impurities in highly pure Mo, sample solution analysis, and ionization mechanisms by glow discharge. The ion intensity was affected by the sample location for discharge, discharge current, and discharge voltage, but not by the sample shape. The maximum ion intensity was obtained when the sample was located 8 mm from the ion slit. After confirming that other conditions had to be set constant, these results were applied to quantization of impurities in highly pure Mo. Relative sensitivity coefficients were determined by the spark ion source mass spectrometry, and satisfactory results were obtained. A solution sampling method was investigated for lesser segregation influences by matrices and elements. Quantization of solution samples was made by dipping a highly pure graphite bar in the solution and doping. The Penning ionization ratio was determined by investigating the elements' ion intensities obtained by using Ar, Kr, and Xe gases. It is determined that there is no difference in the relative sensitivity coefficients between these discharge gases. The Penning ionization ratio is 75 to 85 percent. Author (NASDA)

STUDY ON IMPROVEMENT IN PHYSICAL ANALYSIS METHOD OF METALLIC MATERIALS [KINZOKU ZAIRYO NO BUTSURI BUNSEKI SHUHO NO KODOKA NI KANSURU KENKYU]

Yoshio Tamura, Tsuneo Okoshi, Kazuhiro Honma, Takashi Kimura, Kazuyuki Ogawa, Haruo Doi, and Yukihiro Isoda *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 309-321 In JAPANESE (For primary document see N94-25544 07-26)
Avail: CASI HC A03/MF A04

Refinement of technology for crystal structures was investigated with the purpose of improvement in physical analysis. The research had two themes. One is an analysis by x ray diffraction. The x ray diffraction determining the long periodical structures of binary alloys was extended in order to determine site locations and the mutual substitution amount between Ti and Al elements of ternary TiAl-X alloys. These alloys were produced by adding V, Mn, Zr, or Nb to binary TiAl alloys. It was found that V and Mn atoms were chiefly solid solutionized to Al sites, and Zr and Nb atoms to Ti sites. The mutual substitution amount between Al and Ti atoms decreased as the density of V and Mn increased. The other theme is an analysis by high resolution electron microscopy. Fe 30 mol percent FeO, composed by sintering carbonyl and FeO powders, was observed at Fe/FeO interfaces by a high resolution electron microscope. The results were compared with the composition analysis results of oxidized crystals obtained by Auger electron spectroscopy. Migration areas of distorted FeO cubes with decreased oxygen were generated at (111) Fe/(110) FeO interfaces. Excess oxygen was diffused from FeO in the areas with decreased oxygen, and those areas played a significant role to the joint of Fe/FeO phases.

STUDY ON ANALYZING METHOD ESTABLISHMENT FOR METALLIC MATERIAL DEVELOPMENT [KINZOKUKEI ZAIRYO KAIHATSU NI TOMONAU BUNSEKIHO NO KAKURITSU NI KANSURU KENKYU]

Haruno Okouchi, Osamu Kujirai, Fumio Hirose, Muneyuki Kori, Shunichi Suzuki, Katsuyuki Takahashi, Masayoshi Kiyokawa, Takayuki Yoshioka, Koichi Sato, and Tsuyoshi Kobayashi et al *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 323-335 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A03/MF A04

Research was conducted on the inductively coupled plasma (ICP) emission spectrometry and the graphite furnace atomic absorption spectrometry as means for atomic spectrometry. For the ICP emission spectrometry, simultaneous determination of hydride components (As, Bi, Sb, Se, and Te) in Mo as well as non-hydride components (Co, Cr, Cu, Fe, Mn, Ni, Ti, V, Zn, and Zr) in MoO3 were studied. Direct determination was investigated on Ni base super heat resisting alloys (Al, B, Co, Cr, Cu, Fe, Mn, Mo, Nb, P, S, Si, Ti, and Ta) by spark abrasion/ICP emission spectrometry. For the graphite furnace atomic absorption spectrometry, a series of platform techniques were studied. Determination of acid solubilized and insolubilized Al in steel was also researched. In and Cd in Ni base super heat resisting alloys were studied for direct determination of sample solution. A potential method for direct determination was found after systematic investigation into Pb, Mn, and Co with different melting point. Acid decomposition glass bead/X-ray fluorescence analyses were performed on various superconductors (Bi-, Y-, La-, Nd-, and Ti-groups) as well as seven main elements in Ti alloys. The theoretical acid alpha coefficient method and the fundamental parameter method were compared for matrix correction. Accurate, precise results were obtained. The glow discharge mass analysis method was established for impure rare earth elements in rare earth metals. Si separation by distillation in dystetic metals (Nb, Ta, V, and Zr) and absorptiometric method were established.

STUDY ON VARIATION OF DAMAGE GENERATION MECHANISM BY FATIGUE ON TIAl COMPOUNDS DUE TO DIFFERENT SLIP SYSTEMS [SUBERIKEI NO SA NI MOTOZUKU TIAL NO HIRO SONSHO HASSEI KIKO NO HENKA NI KANSURU KENKYU]

Koji Yamaguchi, Masuo Shimodaira, Kazuo Kobayashi, Minoru Nobuki, and Kenki Hahsimoto *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 337-343 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A02/MF A04

TiAl intermetallic compounds are expected as new, light materials with heat resistance. They also have rare properties, and break by brittleness at 700 C or less, while they break by ductility accompanied by slip distortion at above 700 C. Axial strain control fatigue tests were conducted on such a compound at 800 C and room temperature to study repeated distortion and fatigue strength properties as well as fatigue damage generation mechanisms at different temperatures. The test sample used was Ti(34.7)Al(1.74)V (weight percent) which was uniformly annealed. The fatigue strength of the test sample did not deteriorate as the temperature rose. On the contrary, it showed higher fatigue strength. As for fatigue strength at room temperature, cracks were observed at grain boundaries hitting coarse slip lines at separated slip planes parallel to coarse slip lines and around the intersection of duplex slip lines. The fatigue fracture generated at 800 C was almost the same as that generated at room temperature. However, at 800 C, twin distortion across grain boundaries was noted in addition to slip distortion. This twin distortion caused a intergranular crack at the intersection of grain boundaries and the twin distortion, and the facet was patterned with stripes.

STUDY ON HIGH TEMPERATURE DAMAGE CONTROL AND LIFE IMPROVEMENT [KOON SONSHO SEIGYO TO JUMYO ENCHOKA NI KANSURU KENKYU]

Norio Shinya, Seiichi Ikeda, Junro Kyono, Ryo Horiuchi, Hideo Tanaka, Masaharu Murata, Hideaki Kushima, and Koichi Yagi *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 345-353 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A02/MF A04

Fundamental research was conducted with the purpose of improving the life of heat resisting steel by reducing the occurrence of high temperature damage as well as by recovering from the caused damage. Intergranular creep cavities and surface cracks were studied. The research themes were to: (1) extinguish creep cavities by sintering process; (2) coat creep cavity surfaces with stable deposited materials to freeze the cavity growth; (3) refine the grain of only the surface layers to retard the generation of surface cracks; and (4) propose some concrete ideas on processing to improve the life of heat resisting steel. The sintering rates of creep cavities by simple heating and hydrostatic heating were slow, and both heating methods were effective for minute cavities at early stages of generation, but not for big, grown cracks. On the other hand, compressive stress heating accelerated sintering in creep cavities, extinguishing big crack-like creep cavities. Heat resisting steel of high temperature strength improved by the addition of Ti and V broke in low ductility due to cracks grown from surfaces to grain boundaries. These surface cracks easily occur with large crystals, and accordingly, a method was developed to refine the grains of only surface layers. VN deposition and fine recrystallized grains were obtained to prevent grains from growing. Thus, only the granules at surface layers could be refined, and materials with these surface layers showed excellent mechanical characteristics.

STUDY ON ELUCIDATION OF DAMAGE GENERATION PROCESS BY ELECTRON BEAM LITHOGRAPHY [DENSHISEN RISOGURAFI NI YORU SONSHO KATEI NO KAIMEI NI KANSURU KENKYU] c39

Norio Shinya, Satoshi Kishimoto, Mitsuru Egashira, Junro Kyono, and R. A. Carolan *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 355-361 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A02/MF A04

Two micro-deformation measurement methods were developed to assess local micro-deformations that lead to damages in materials as well as to analyze the damage generation process. The two methods, both utilizing electron beam lithography, were the microgrid method (direct measurement of microgrids) and the electron moire method (electron beam scanning). With these methods, creep micro-deformations were observed and measured on metallic materials. The slip amount and creep strains were different at each grain boundary or crystal grain. Creep strains were not uniform even in the same grain boundary: high tension strained areas and low strained areas alternate and formed stripe patterns. This ununiformity in distribution was related to the grain boundary slip and cracking. High strains were observed around the areas with grain boundary slip, whereas the strains around the areas with no grain boundary slip were low. Simulation of creep deformation was made on a computer by the polycrystal limited factor model which was developed considering the different grain boundary slips. The results were quite similar to those from the experiments with electron beam lithography, and it was confirmed that uneven strains in creep grains of polycrystal metals were closely related to the grain boundary slip. STUDY ON PERFORMANCE EVALUATION OF PRESSURE VESSEL STEEL IN CORROSION ENVIRONMENTS WITH SULFIDE [RYUKABUTSU KANKYO NI OKERU ATSURYOKU YOKIKO NO SEINO HYOKA NI KANSURU KENKYU]

Takao Aoki and Keiji Nakano *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 363-367 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A01/MF A04

Research was conducted on the stress corrosion fracture behaviors of sulfide in high tensile steel by performing a low strain rate test and studying the effects caused by environmental factors. The purpose of the research is to check if chloride solution containing S2O3(2-) was suitable for moist hydrogen sulfide environments. This was considered to be a better method to replace the hydrogen sulfide addition method which is currently adopted but is quite dangerous. The maximum ductility deterioration by hydrogen absorption in high tensile steel was detected when the Na2S2O3 density was 10(exp -3) mol/l during the low strain rate test. The corrosion environment in the test solution was as severe as that in NACE (National Association of Corrosion Engineers) TM0284-86 solution, but slightly milder than that in NACE TM0177-86 solution (standard NACE solution). More hydrogen was absorbed in steel as the amount of Na2S2O3 increased. However, once the absorbance reached saturation (10(exp -2) mol/l or more), sulfide scales were generated on metal surfaces, and absorption declined. Author (NASDA)

Avail: CASI HC A02/MF A04

Creep, crack generation under creep fatigue, and creep crack growth were investigated in correlation with microscopical observation with the purpose of improving the evaluation level of creep crack growth behaviors and rupture lives under creep-fatigue loading. A creep crack growth test was conducted on 316 stainless steels and NCF800H alloys to find the correlation between the creep crack growth rate (da/dt) and the breaking style parameter C. The results showed that the da/dt-C correlation was closely related to the breaking style, and it could be classified into two groups based on the breaking style. However, this correlation was not true if a creep damage ranged over a large area around the crack end. A creep fatigue test was conducted under combined loading on coarse grained and fine grained 321 stainless steels. Determination of the creep damage amount and fatigue damage amount by linear life damage rules revealed that the correlation between these two amounts was related to the breaking style, and furthermore, to the breaking process as well. STUDY ON FATIGUE CRACK PROPAGATION CHARACTERISTICS AROUND WELDED JOINT INTERFACE IN COMPLEXED CONDITIONS [KANKYOKA NI OKERU SETSUGO KAIMEN KINBO NO HIRO KIRETSU DENPA TOKUSEI HYOKA NI KANSURU KENKYU] **c39**

Akihiko Ota, Naoyuki Suzuki, Yoshio Maeda, Toshio Mawari, Saburo Matsuoka, and Satoshi Nishijima *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 379-386 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A02/MF A04

Marine structures are often constructed by welding, and they are subject to repeated loading such as waves and mechanical vibrations which can create fatigue cracks and consequently break the structures. Fatigue crack propagation properties of welded joints are studied under random loading in the air, synthetic sea water, and compressive cycling. It was found that the most crucial factor that controls fatigue crack propagation was high tensile residual stress fields of welded joints. This stress constantly kept the cracks open, simplifying fatigue crack propagation, and therefore, the rate of crack propagation could be assessed with high accuracy. In the transverse matching welded joints with cracks in the center, crack closure did not occur due to the tensile residual stress constantly induced at the crack ends in the center of the test samples. Fatigue crack propagation was accelerated both in artificial sea water and in compressive cycling compared to that in the air, and the fatigue lowest values were about half. Serious crack closures occurred in compressive cycling in which dry hours exceeded 45 minutes, and the fatigue crack propagation rate deteriorated remarkably. Mean fatigue crack propagation rate under the random loading is estimated precisely using equivalent stress intensity factor limit. Author (NASDA)

STUDY ON MELTED SOLUTION STIRRING UNDER MICROGRAVITY [BISHO JURYOKU KANKYO NI OKERU YUEKI NO KAKUHAN NI KANSURU CHOSA KENKYU] **c29**

Akira Sato, Ken Sasabe, Isao Nakatani, Kiyoshi Ozawa, Akira Fukuzawa, Kazuyuki Sakuraya, Kazumasa Togano, Hiroaki Kumakura, Daniel Robert Dietdrich, and Masao Takeyama et al *In its* Bulletin of National Research Institute for Metals in Fiscal Year 1993, No. 14 29 Jan. 1993 p 387-392 In JAPANESE (For primary document see N94-25544 07-26)

Avail: CASI HC A02/MF A04

The techniques of stirring and stopping the melted solution are studied for experiments to create materials to be used for Japanese Experiment Module (JEM) in space stations. The following results were obtained: (1) since the required material has to be solid and then melted and solidified again, mixing fins must be either put in/out in the melted solution or they must be solidified with alloys (if this issue is solved, fins will be effective under microgravity, and also convenient for experiments on a large scale); (2) there has not been many examples of sound wave or ultrasonic wave vibrations having been applied to material processing except for experiments on crystal refinement at solidification (mixing effects under normal gravity must be investigated first); (3) material processing by induction generates heat (there is more potential for utilizing electromagnetism under microgravity than under normal gravity, because little electric power is required to control melted materials under microgravity); (4) material property values must be assessed first before utilizing convection in mixing; and (5) under microgravity, it is possible to mix/stop mixing melted solution by generating artificial gravity. However, this seems to be more effective for removing bubbles and inclusions than for mixing. Author (NASDA)

Creation of new materials is entering a new phase with recent development in control and analysis technologies. Nowadays, it is becoming possible to freely control individual atoms, ions, electrons, and photons. However, technologies in metallic materials are not yet ready for super high vacuum environment unlike those in semiconductors. A new field in metallurgy will start with the creation of new materials by dealing with super pure material atoms individually on clean surfaces and interfaces in special research institutions. Such institutions should provide super clean, high vacuum environment to allow a series of processes from refinement, synthesis, and processing to evaluation. For this purpose, it is important to establish a transportation system where equipment relevant to material creation is all connected in super clean, high vacuum so that samples can be transported between equipment to minimize changes in material quality. These institutions are likely to be used for joint researches, and the first issue to arise will be management and administration of this transportation system in high vacuum. Secondly, there is an issue of the parties to be responsible for administration/management of main equipment on each line. Researchers that may utilize these institutions must be considered as well. WELDABILITY OF DIRECT-QUENCHED AND TEMPERED (DQT) HIGH STRENGTH STEEL HT80

Pekka Nevasmaa, Mark Cederberg, and Martti Vilpas Oct. 1992 42 p
Sponsored by Nordisk Industrifond; Technology Development Center, Finland; and Technical Research Centre of Finland, Espoo
(ISSN 1235-0621)
(VTT-TIED-1406; ISBN-951-38-4300-9; ETN-94-95251) Copyright Avail: CASI HC A03/MF A01

The test results obtained in welding and weldability tests of a Direct Quenched and Tempered steel DQT HT80 are discussed. The tests comprised mechanical testing of joints welded with arc energies of 20 and 45 kJ/cm using Submerged Arc Welding (SAW) and Flux Cored Arc Welding (FCAW) processes. The results of weld thermal simulation and implant weldability tests for the steel are reported. The results demonstrate the improved weldability of the DQT HT80 steel, as compared to quenched and tempered steels of similar strength level. The need for preheat was found 70 to 90 C lower for the DQT steel. Cracking of weld metal suggested that increasing preheat and interpass temperatures become necessary with heavier plate thicknesses of 40 mm and above. SAW yielded higher weld metal toughness than FCAW. The maximal hardness properties of DQT HT80 steel were found to deteriorate as the arc energy increased from 20 to 45 kJ/cm. The Charpy 5 tests confirmed the tendency of decreasing toughness with prolonged cooling times. ESA

COMPUTER AIDED SIMULATION OF HEAT TREATMENT

Raimo Arola, Hannu Martikainen, and Jouko Virta Jan. 1993 50 p
Sponsored by Nordic Industrial Fund; Technology Development Center of Finland; and Technical Research Centre of Finland, Espoo Original contains color illustrations
(ISSN 1235-0621)
(VTT-PUBS-131; ISBN-951-38-4249-5; ETN-94-95238) Copyright Avail: CASI HC A03/MF A01

Computer aided simulation of the heat treatment of components and charges is examined. Programs for the simulation of heat treatment are reviewed. Test simulations including calculation of temperature, phase composition, and stresses and strains during heating and cooling are performed. The results of the simulations and the results of heat treating experiments are compared. Heat transfer during heating up varies between different treatments, components of the charge, and surfaces of the component. Heat transfer data defined on the basis of the measurements instead of literature data were used. Plastic straining and residual stresses after heating can be formed in an AISI 316 bar heated up at the edge of the charge in a pit furnace. Permanent bending of these bars as a result of heating is not observed. In the oil quenching of a 42CrMo4 cylinder, where martensite and bainite are formed in austenite decomposition, the simulation results depend on the TTT (Time Temperature Transformation) diagram. Several TTT diagrams for the steel grade are found. ESA

WELDABILITY OF ACCELERATED-COOLED (AcC) HIGH STRENGTH TMCP STEEL HT50

Pekka Nevasmaa, Mark Cederberg, and Martti Vilpas Oct. 1992 40 p
Sponsored by Nordisk Industrifond; Technology Development Center, Finland; and Technical Research Centre of Finland, Espoo
(ISSN 1235-0621)
(VTT-TIED-1410; ISBN-951-38-4304-1; ETN-94-95252) Copyright Avail: CASI HC A03/MF A01

The test results obtained in welding and weldability tests of two Accelerated Cooled AcC Thermomechanically Processed (TMCP) HT50 class steels are discussed. The tests comprised mechanical testing of joints welded with arc energies ranging from 10 to 100 kJ/cm using Submerged Arc Welding (SAW) and Flux Cored Arc Welding (FCAW) processes. The results of weld thermal simulation and implant weldability tests are reported. The results demonstrate the excellent weldability of AcC HT50 steels, as compared to normalized or quenched and tempered steels of similar strength level. Welding without preheat was possible up to 50 and 60 mm plate thickness using low arc energies of 10 and 22 kJ/cm, respectively, provided that redried electrodes are used. For the arc energy range used with SAW and FCAW, weld metal toughness properties were found to be adequate. Excellent maximal hardness low temperature toughness properties were demonstrated in Charpy 5 tests. All AcC YS 420 steel weldments fulfilled the impact energy requirement in the arc energy range of 10 to 50 kJ/cm. Charpy 5 tests of simulated hardness measurements confirmed that there were no significant changes in the toughness level with the weld cooling time t(sub 8/5) between 12 and 52 seconds. ESA

MICROSTRUCTURAL DEVELOPMENT IN LOW ACTIVATION FERRITIC ALLOYS IRRADIATED TO 200 dpa AT 420 C

D. S. Gelles 1993 11 p Presented at the 6th International Conference on Fusion Reactor Materials, Stresa, Italy, 27 Sep. - 1 Oct. 1993
(Contract DE-AC06-76RL-01830)
(DE94-004269; PNL-SA-22526; CONF-930928-21) Avail: CASI HC A03/MF A01

Density change and microstructural development are reported for nine low activation ferritic steels covering the range 2.3 to 12 Cr with varying additions of V and/or W for hardening and up to 6.5 Mn for austenite stability. Specimens were examined following irradiation in FFTF/MOTA at 4200 C to a dose exceeding 200 dpa. Void swelling was found, but the swelling remained at 5% or below, with the worst case in an alloy of 9Cr-2Mn-1WV. The carbide structure pinning Martensite lath boundaries remains in place. DOE

RADIATION HARDENING EFFECTS ON LOCALIZED DEFORMATION AND STRESS CORROSION CRACKING OF STAINLESS STEELS

S. M. Bruemmer, J. I. Cole, J. L. Brimhall, R. D. Carter (Michigan Univ., Ann Arbor.), and G. S. Was (Michigan Univ., Ann Arbor.) Aug. 1993 9 p Presented at the 6th International Symposium on Environmental Degradation of Materials in Nuclear Power Systems: Water Reactors, San Diego, CA, 3-5 Aug. 1993
(Contracts DE-AC06-76RL-01830; DE-FG02-93ER-12130)
(DE94-004308; PNL-SA-21725; CONF-930825-14) Avail: CASI HC A02/MF A01

Radiation hardening in austenitic stainless steels modifies deformation characteristics and correlate well with increased susceptibility to intergranular stress corrosion cracking (IGSCC). Available data on neutron-irradiated materials have been analyzed and correlations developed between fluence, yield strength, and cracking susceptibility in high-temperature water environments. Large heat-to-heat differences in critical fluence (0.2 to 2.5 x 10(exp 21) n/cm(exp 2)) for IGSCC are documented. In many cases, this variability is consistent with yield strength differences among irradiated materials. IGSCC correlates better to yield strength than to fluence for most heats suggesting a possible role of radiation-induced hardening (and microstructure) on cracking. Microstructural evolution during proton and heavy-ion irradiation has been characterized in low-carbon 302SSs. Hardening results from dislocation loops. SEM and TEM are used to examine dose, strain, and temperature effects on deformation. This hardened microstructure produces inhomogeneous planar deformation within the matrix. Regularly spaced steps are created at the surface during deformation which increase in number with increasing macroscopic strain. Twinning is the dominant deformation mechanism at low temperature, while dislocation channeling is observed at 288 C. Deformation characteristics are discussed in terms of potential impact on IGSCC. ISSUES FOR CONVERSION COATING OF ALUMINUM ALLOYS WITH HYDROTALCITE

C. A. Drewien and R. G. Buchheit 1993 10 p Presented at the Corrosion 1994: National Association of Corrosion Engineers International Annual Conference, Baltimore, MD, 28 Feb. - 4 Mar. 1994
(Contract DE-AC04-94AL-85000)
(DE94-003804; SAND-93-2205C; CONF-940222-6) Avail: CASI HC A02/MF A01

Hydrotalcite coatings on aluminum alloys are being developed for corrosion protection of aluminum in aggressive saline environments. Coating bath composition, surface pretreatment, and alloying elements in aluminum all influence the performance of these coatings during salt spray testing. The coating bath, comprised of lithium carbonate, requires aging by dissolution of aluminum into the bath in order to grow corrosion resistant coatings. Coatings formed in non-aged baths do not perform well in salt spray testing. The alloying elements in aluminum alloys, especially copper, influence the coating growth and formation leading to thin coatings. The effect of the alloy elements is to limit the supply of aluminum to the coating/electrolyte interface and hinder growth of hydrotalcite upon aluminum alloys. DOE

EFFECT OF NITROCARBURIZING ON SHAPE OF TITANIUM ALLOY PARTS

E. A. Clark 27 Sep. 1993 20 p
(Contract DE-AC09-89SR-18035)
(DE94-004040; WSRC-TR-93-474) Avail: CASI HC A03/MF A01

Components are being developed for plutonium casting in support of Lawrence Livermore National Laboratory. A vendor used a proprietary process to grow a nitrocarburized surface layer on a titanium alloy shot sleeve to be used in a prototype die casting machine. The shot sleeve was significantly out-of-round upon return from the vendor and could not be used. Purpose of this study was to determine whether the shape change could have been caused by this surface treatment. Visual observation of disk and ring samples exposed first to surface treatment alone temperature and then the actual nitrocarburizing environment revealed no gross warping in either case. Dimension measurements of each sample before and after both the thermal treatment and the nitrocarburizing revealed no significant changes. Visual examination of the shot sleeve revealed a surface flaw likely made during handling after machining at SRS and before the part was nitrocarburized. The out-of-roundness of the shot sleeve could be related to the damage observed on the surface, but the possibility of warping during the nitrocarburizing cannot be excluded. Nitrocarburization should remain a candidate method to protect titanium alloys from molten metals. DOE

DISSOLUTION OF SECONDARY PHASES DURING EXTRUSION

U. H. Tundal 3 May 1993 7 p Sponsored by Hydro Aluminum A/S
(PB94-124583; STF34-A93094) Avail: Issuing Activity (National Technical Information Service (NTIS))

The report is a summary of the presentation made by U. Tundal at the seminar on the EXPOMAT EXTRUSION PROJECT at Karmoy, Norway, May 4, 1993. The title of the presentation was 'Growth and dissolution of Magnesium Silicide-particles'. First, some results from the Doctoral Thesis on 'Dissolution of Particles in Binary Alloys' were presented. Then a brief introduction to the project on modeling growth and dissolution of particles in connection to the extrusion process was made. NTIS

THE ROLE OF GRAIN BOUNDARY CHEMISTRY AND STRUCTURE IN THE ENVIRONMENTALLY-ASSISTED INTERGRANULAR CRACKING OF NICKEL-BASE ALLOYS

G. S. Was 1993 19 p
(Contract DE-FG02-85ER-45184)
(DE94-003159; DOE/ER-45184/9) Avail: CASI HC A03/MF A01

Progress focused on determination of the role of C and Cr on deformation and IG cracking behavior of Ni(5-30)Cr9Fe, determination of the effect of grain boundary misorientation on IG cracking behavior, construction of an electron backscattering pattern (EBSP) imaging system, determination of effect of the environment on creep and cracking, and characterization of the surface film. Results showed that both C and Cr are potent solid solution strengtheners which can reduce the steady state creep rate at 360 C by several orders of magnitude. Intergranular cracking of 100 micron grain samples of high purity Ni16Cr9Fe at 360 C occurs by formation of grain boundary voids and interlinkage, driven by dislocation creep in the matrix. Creep experiments in primary water at 360 C and an applied cathodic potential show that the creep rate is increased by an order of magnitude over that in Ar and the percent IG fracture increases as well. Oxide film composition and thickness is a sensitive function of the C content, increasing in thickness and Ni(OH)2 content with increase in C or decrease in Cr to 5 wt%. Thermomechanical treatments along with electron channeling pattern (ECP) analysis were used to create and index samples with enhanced fractions of coincident site lattice boundaries (CSLB's). Constant extension rate tensile (CERT) experiments on samples with a high percentage of CSLB's showed IG cracking compared with general high angle boundaries. However, these experiments were conducted on grain sizes of 300 microns, while commercial material is an order of magnitude smaller. An electron backscattering pattern imaging system has been constructed for an environmental scanning electron microscope which can image grains below five micron. The system has been successfully benchmarked against results from ECP analysis. DOE

EFFECT OF LOADING MODE ON THE FRACTURE TOUGHNESS OF A REDUCED ACTIVATION FERRITIC/MARTENSITIC STAINLESS STEEL

H. Li (Washington State Univ., Pullman.), J. P. Hirth (Washington State Univ., Pullman.), R. H. Jones, and D. S. Gelles Sep. 1993 20 p Presented at the 6th International Conference on Fusion Reactor Materials, Stresa, Italy, 27 Sep. - 1 Oct. 1993
(Contract DE-AC06-76RL-01830)
(DE94-004290; PNL-SA-22545; CONF-930928-16) Avail: CASI HC A03/MF A01

The critical J integrals of mode 1 (J(sub 1C)), mixed-mode 1/3 (J(sub MC)), and mode 3 (J(sub 3C)) were examined for a ferritic stainless steel (F-82H) at ambient temperature. A determination of J(sub MC) was made using modified compact-tension specimens. Different ratios of tension/shear stress were achieved by varying the principal axis of the crack plane between 0 and 55 deg from the load line. The results showed that J(sub MC)s and tearing moduli (T(sub M)) varied with the crack angles and were lower than their mode 1 and mode 3 counterparts. Both the minimum J(sub MC) and T(sub M) occurred at a crack angle between 40 and 50 deg, where (sigma)(sub i)/(sigma)(sub iii) was 1.2 to 0.84. The J(sub min) was 240 kJ/sq m, and ratios of J(sub 1C)/J(sub min) and J(sub 3C)/J(sub min) were about 2.1 and 1.9, respectively. Morphology of fracture surfaces was consistent with the change of J(sub MC) and T(sub M) values. While the upper shelf-fracture toughness of F-82H depends on loading mode, the J(sub min) remains very high. Other important considerations include the effect of mixed-mode loading on the DBT temperature, and effects of hydrogen and irradiation on J(sub min). DOE

DEVIATORIC STRESSES AND PLASTIC STRAIN RATES IN STRONG SHOCK WAVES FOR SIX METALS
D. L. Tonks Nov. 1993 32 p
(Contract W-7405-eng-36)
(DE94-002964; LA-12641) Avail: CASI HC A03/MF A01

The strong shock theory of D. C. Wallace (Phys. Rev. B24, 5597 (1981) and Phys. Rev. B24, 5607 (1981)) is used to calculate the shock structure for 1100 Al, 2024 Al, Cu, Fe, Ta, and U. Emphasis is given to the behavior of plasticity, i.e., average deviatoric stresses, plastic and total strains, and strain rates, which are given in figures for a number of shock strengths. This information will be useful for modeling plasticity in metals under extreme conditions. It was used for part of the PTW model for mechanical behavior. DOE

N94-26069# Los Alamos National Lab., NM.
DEBYE-WALLER FACTORS OF THE LIGHT ACTINIDE METALS
A. C. Lawson, J. A. Goldstone, B. Cort, R. I. Sheldon, and E. M. Foltyn 1993 15 p Presented at the Actinides 1993; 1994 TMS Annual Meeting on Actinides, Santa Fe, NM; San Francisco, CA, 19-24 Sep. 1993; 27 Feb. - 3 Mar. 1994
(Contracts W-7405-eng-36; W-31-109-eng-38)
(DE94-000685; LA-UR-93-3463; CONF-930905-9; CONF-940221-1) Avail: CASI HC A03/MF A01

Time-of-flight neutron powder diffraction was used to determine the Debye-Waller factors of light actinide metals. The Debye-Waller factor is a measure of the mean-square atomic displacement that arises from the thermal motion of the atoms in any solid. Its temperature dependence determines a Debye-Waller temperature, Theta(sub DW), that is characteristic of the elastic properties of the solid. The data are obtained by Rietveld analysis of neutron diffraction powder patterns obtained at several temperatures. Results are presented for alpha-U, alpha-Np, alpha-Pu and delta-Pu(0.95)Al(0.05). The Theta(sub DW)'s are temperature dependent, and anharmonic interatomic forces seem to be required to explain the results. DOE

SURFACE PHYSICS WITH COLD AND THERMAL NEUTRON REFLECTOMETRY
A. Steyerl Sep. 1993 23 p
(Contract DE-FG02-91ER-45445)
(DE94-001447; DOE/ER-45445/9) Avail: CASI HC A03/MF A01

Within the past two and one half years of the project 'Surface Physics With Cold and Thermal Neutron Reflectometry' a new thermal neutron reflectometer was constructed at the Rhode Island Nuclear Science Center (RINSC). It was used to study various liquid and solid surfaces. Furthermore, neutron reflection experiments were begun at different laboratories in collaboration with Dr. G.P. Fetcher (at Argonne National Laboratory), Dr. T. Russell (IBM Almaden), and Drs. S.K. Satija and A. Karim (at the National Institute for Standards and Technology). The available resources allowed partial construction of an imaging system for ultracold neutrons. It is expected to provide an extremely high resolution in momentum and energy transfer in surface studies using neutron reflectometry. Much of the work reported here was motivated by the possibility of later implementation at the planned Advanced Neutron Source at Oak Ridge. In a separate project, the first concrete plans for an intense source of ultracold neutrons for the Advanced Neutron Source were developed. DOE

ALUMINUM-ION SPUTTERING FROM Al SURFACES WITH VERY-LOW-ENERGY IONS
Michio Okada and Yoshitada Murata Apr. 1993 35 p Sponsored by Ministry of Education, Science and Culture, Tokyo, Japan and Japanese Society for the Promotion of Science, Tokyo, Japan
(ISSN 0082-4798)
(Rept-A-2668; JTN-94-80539) Avail: CASI HC A03/MF A01

Sputtering of Al(+) for N2(+), N(+), and Ne(+) incidence was observed at the threshold energy of approximately 20 eV. The polar-angle distribution of the sputtered Al(+) ions gives almost the same lobe position at different angles of incidence. In N(+) and Ne(+) incidence on the Al (111) surface, a sharp structure which correlates with the crystal structure, was observed in the angular distribution of the sputtered Al(+) ions. In ion incidence on the open surface of Al (110), chemical interaction between a projectile and the target material plays an important role in the sputtering process. The mechanisms of ion sputtering induced by very low-energy ions (less than or equal to 200 eV) are discussed. Author (NASDA)

INFLUENCE OF GRAIN STRUCTURE AND SOLUTE COMPOSITION ON THE WORK HARDENING BEHAVIOR OF ALUMINIUM AT CRYOGENIC TEMPERATURES
D. Chu and J. W. Morris, Jr. Jul. 1993 10 p Presented at the International Cryogenic Engineering Conference and International Cryogenic Materials Conference, Albuquerque, NM, 12-16 Jul. 1993
(Contract DE-AC03-76SF-00098)
(DE94-003415; LBL-34019; CONF-930703-38) Avail: CASI HC A02/MF A01

An unrecrystallized structure is found to significantly improve work hardening characteristics by lowering the work hardening rate during the early stages of deformation. This is in contrast to a recrystallized structure, which requires a higher work hardening rate to accommodate the greater degree of multiple slip necessary to maintain strain compatibility between the more randomly oriented grains. The stronger texture associated with the unrecrystallized structure allows deformation to occur more efficiently. Addition of magnesium also improves work hardening by increasing overall level of the work hardening rate. The improved characteristics of the work hardening behavior result in a parallel increase in both the strength and ductility at cryogenic temperatures. These findings are positive since they suggest a method by which improvements in the work hardening behavior and subsequent mechanical properties may be obtained through practical modifications of the microstructure and composition. DOE

STRUCTURE OF THE MODULATED MAGNETIC PHASE OF Mn3Sn
J. W. Cable, N. Wakabayashi (Keio Univ., Yokahama, Japan.), and P. Radhakrishna (Indian Inst. of Science, Bangalore.) 1993 14 p Presented at the 38th Annual Conference on Magnetism and Magnetic Materials, Minneapolis, MN, 15-18 Nov. 1993
(Contract DE-AC05-84OR-21400)
(DE94-002788; CONF-931133-6) Avail: CASI HC A03/MF A01

The triangular antiferromagnetic order that occurs in hexagonal Mn3Sn below 420 K becomes modulated below 270 K in what is generally described as a helical modulation propagating along the c axis with a period of about 10 or 12 c(sub 0). However, such a modulation is inconsistent with a recently observed energy gap in the magnetic excitation spectra for this phase. The magnetic structure of this modulated phase was reexamined by neutron diffraction and two distinct modulations were found, both propagating along the c axis and both with periods that are commensurate with the lattice below about 120 K. The satellite reflections associated with these two modulations have quite different intensities and temperature dependences suggesting coexistent modulated phases. For the dominant 11 c(sub 0) phase, a third harmonic is observed with an intensity that is four percent of the first harmonic but no fifth or seventh harmonic is found to a sensitivity of about 10(exp -4). The presence of this third harmonic shows a significant distortion of the helical modulation wave. The observed harmonic intensity distribution was compared with magnetic structure factor calculations for configurational models with moment directions bunched around the easy axes in the basal plane. The results of this comparison are given in this paper. DOE

Heavy Ions Rutherford Backscattering Spectrometry (HIRBS) was used to analyze diffusion profiles. Penetrations of about a micron were measured; in this form it was possible to complete the range of temperature of diffusion studies in the hop phase of Ti extending it until the overlap with even lower temperatures measured previously with RBS. The ion-material interaction along the trajectory of the heavy ion beam was considered in the method developed to convert HIRBS spectra in diffusion profiles. The results obtained for Zr and Hf diffusion in Ti in the range 1133 - 823 K for Zr and 1145 - 823 K for Hf are discussed in this paper. DOE

Zr-RICH CORNER OF THE Zr-Sn-O DIAGRAM [ESQUINA RICA EN COMPOSICION DE CIRCONIO DEL DIAGRAMA ZR-SN-O]

L. A. Roberti, D. E. Arias, and L. Gribaudo (Consejo Nacional de Investigaciones Cientificas y Tecnicas, Buenos Aires, Argentina.) 1993 6 p In SPANISH Presented at the SAM 1993: 17th Metallurgical Sessions of the Argentine Metals Association; 2nd Argentine Meeting on Ceramics and Refractories, San Carlos de Bariloche, Argentina, 13-16 Apr. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-633764; INIS-AR-021; CONF-9304174) Avail: CASI HC A02 (US Sales Only)

The understanding of the effect of light elements (in particular, oxygen, nitrogen, and hydrogen) on the behavior of alloys for nuclear use is necessary because of its technological importance. The Zr-Sn-O system is perhaps the most representative of all possible ternary systems which can be used to simulate a simplified Zircaloy-type alloy in which the effect of O can be studied. However, in the specialized literature, experimental data on phase equilibria and thermophysical properties of this system are not easily found. In the present work, the equilibrium compositions of the alpha and beta phases of the Zr-Sn-O system at temperatures between 1150 and 1323 K are calculated, using the scarce available information. First results of the calculations show satisfactory coincidences with experimental data. Future work will be oriented towards the proposal of isothermal cross-sections calculated by a modelling of phases with wider Sn and O composition ranges, and involving equilibria with the phases Zr4Sn, Zr5Sn3, ZrO2, ZrSnO4. (DE93-633765; INIS-AR-022; CONF-9304174) Avail: CASI HC A02 (US Sales Only)

This paper describes the tests conducted to determine the conditions leading to cracking of a specified grain of metal, focusing on the crystallographic orientation of crack paths, the critical stress conditions and the significance of the fractographic features encountered. In order to get orientable cracking, a technique was developed to produce iodine SCC, by means of pressurizing tubes of a specially heat treated Zry-4 having very large grains, shaped as discs of a few millimeters in diameter and grown up to the wall thickness. Careful orientation of fractured grains, performed by means of a back-reflection Laue technique with a precision better than one degree, has proved that transgranular cracking occurs only along basal planes. The effect of anisotropy, plasticity, triaxiality and residual stresses originated in thermal contraction has to be considered to account for the influence of the stress state. A grain by grain calculation led to the conclusion that transgranular cracking always occurs on those bearing the maximum resolved tensile stress on basal planes. There are clear indications of the need of a triaxial stress state for the process to occur. Fracture modes other than pseudo-cleavage have been encountered, including intergranular separation, ductile tearing produced by prismatic slip, and propagation along twin boundaries. In each case, the fractographic features have been identified, and associations have been made with fractographs obtained in normal fuel cladding. DOE

Zr-Sn-Nb ALLOYS: PRELIMINARY STUDIES [ALEACION ZR-SN-NB. TRABAJOS PRELIMINARES]

C. A. Danon and D. E. Arias 1993 5 p In SPANISH Presented at the SAM 1993: 17th Metallurgical Sessions of the Argentine Metals Association; 2nd Argentine Meeting on Ceramics and Refractories, San Carlos de Bariloche, Argentina, 13-16 Apr. 1993
(DE93-633767; INIS-AR-024; CONF-9304174) Avail: CASI HC A01/MF A01 (US Sales Only)

Studies of the Zr-Sn-Nb diagram have been started, focussing on the Zr-rich corner, near the composition of Zirlo commercial alloy, Zr-1Sn-1Nb, and with Fe and O contents usual in nuclear grade materials. Three alloys were melted, namely Zr-4Sn-2.4Nb (A), Zr-1Sn-3Nb (B) and Zr-2.1Sn-1Nb (C). Alpha/beta transformation temperatures were measured through the variation of electrical resistivity(p) vs temperature (T). Values of 560 deg C, 670 deg C and 750 deg C were measured for the alpha yields alpha+beta reaction and 980 deg C, 910 deg C and 1000 deg C for the alpha+beta yields beta reaction, for the A, B and C alloys, respectively in that order. Some samples were submitted to heat treatments (62 and 216 hours at 825 deg C, 120 hours at 875 deg C). Optical and scanning electronic microscopy of those samples confirmed our resistivity results. STRESS CORROSION CRACKING AND DEALLOYING OF COPPER-GOLD ALLOY IN IODINE VAPOR [CORROSION BAJO TENSION Y DEALEADO DEL COBRE-ORO EN ATMOSFERA DE IODO]

M. F. Galvez, G. L. Bianchi, and J. R. Galvele 1993 6 p In SPANISH Presented at the SAM 1993: 17th Metallurgical Sessions of the Argentine Metals Association; 2nd Argentine Meeting on Ceramics and Refractories, San Carlos de Bariloche, Argentina, 13-16 Apr. 1993
(DE93-633790; INIS-AR-026; CONF-9304174) Avail: CASI HC A02/MF A01 (US Sales Only)

The susceptibility to stress corrosion cracking of copper-gold alloy in iodine vapor was studied and the results were analyzed under the scope of the surface mobility stress corrosion cracking mechanism. The copper-gold alloy undergoes stress corrosion cracking in iodine. Copper iodide was responsible of that behavior. The copper-gold alloy shows two processes in parallel: stress corrosion cracking and dealloying. As was predicted by the surface mobility stress corrosion cracking mechanism, the increase in strain rate induces an increase in the crack propagation rate. DOE

AN ATOM PROBE INVESTIGATION OF THE INFLUENCE OF TRACE IMPURITIES ON THE MECHANICAL BEHAVIOR OF NiAl

R. Jayaram, C. T. Liu, and M. K. Miller 1993 10 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contract DE-AC05-84OR-21400)
(DE94-002797; CONF-931009-11) Avail: CASI HC A02/MF A01

Atom probe field ion microscopy (APFIM) and transmission electron microscopy (TEM) have been used to investigate the influence of trace metallic impurities on the enormous increase in the yield stress of boron-doped NiAl. Previous atom probe studies of NiAl containing 0.12 at. % boron had demonstrated that 0.026 at. % of the boron was in solid solution. The remainder reacted with trace metallic impurities, presumably present in high purity Ni, to form ultrafine MB2 precipitates ranging in size from less than 2 nm to 20 nm. Atom probe measurements had shown that their number densities were significant enough to make the dominant contribution to the observed increase in yield stress. An attempt was made in the present work to minimize the effect of these precipitates by an additional aging treatment. Field ion microscope (FIM) and TEM micrographs revealed that 2 nm precipitates coarsened significantly during aging. Microstructure of aged NiAl was consistent with observed mechanical behavior showing a significantly smaller increase in the yield stress. An approximate value of the Orowan stress, based on TEM estimates of the size and number density of the precipitates, is in reasonable agreement with the measured value. This APFIM/TEM investigation has indicated a practical approach to minimize the detrimental role of trace impurities in NiAl. DOE

LIQUID AND SOLID SOLUBILITY OF Ag IN Bi2Sr2CaCu2O8
R. W. McCallum, K. W. Dennis, L. Margulies, and M. J. Kramer 1993
11 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contract W-7405-eng-82)
(DE94-002829; IS-M-776; CONF-931009-13) Avail: CASI HC A03/MF A01

Currently, leading candidates for usable high temperature superconducting wires are Bi-Sr-Ca-Cu-O tapes produced by modifying the powder in tube process. In order to obtain crystallographic texture, these tapes are processed by partial melting then slow cooling through the peritectic. While it is well known that Ag suppresses the lowest liquidus temperature of the Bi based materials, no serious investigation of the Bi-Sr-Ca-CuO-Ag phase diagram has been undertaken. Solubilities of Ag in Bi2212 melt was determined by ICP-AES and TEM/EDS on samples of Bi2212 and 20 wt % Ag which were melt-spun in air at temperatures of 900 to 1200 C. The most prominent feature of the phase diagram was found to be liquid immiscibility at all temperatures. There exists a eutectic on each side of this gap. For the Ag rich side the eutectic is at 98 at. % Ag and depresses the melting by 15 C over that for pure silver for the same oxygen partial pressure. The oxide rich eutectic contains no more than 4 at % Ag and depresses the solidus by 30 C. The solid solubility of Ag in Bi-Sr-Ca-Cu-O glass (oxide glass) is found to be less than the detection limits of TEM/EDS and Ag is systematically excluded from the oxide glass. DOE

ANALYSIS OF THE EFFECT ON GROWTH KINETICS OF GAMMA PRIMA PHASE IN INCONEL 713C ALLOYS [ANALISIS DE LA CINETICA DE CRECIMIENTO DE LA FASE GAMMA PRIMA EN LA ALEACION INCONEL 713C]
S. I. Thorp (Buenos Aires Univ., Argentina.), R. A. Versaci, A. Ges (Universidad Nacional del Centro de la Provincia de Buenos Aires, Tandil, Argentina.), and H. A. Palacio (Universidad Nacional del Centro de la Provincia de Buenos Aires, Tandil, Argentina.) 1993 6 p In SPANISH Presented at the SAM 1993: 17th Metallurgical Sessions of the Argentine Metals Association; 2nd Argentine Meeting on Ceramics and Refractories, San Carlos de Bariloche, Argentina, 13-16 Apr. 1993
(DE93-633763; INIS-AR-019; CONF-9304174) Avail: CASI HC A02/MF A01 (US Sales Only)

This work shows the analysis of the effect on growth kinetics of gamma prima phase in Inconel 713C alloy of two thermic treatments. In this study, SEM are used and the results are analyzed by means of the theory developed by Lifshitz, Slyozov and Wagner (LSW theory). The findings have revealed that with such theory it is not possible to determine if the process of growth is controlled either through diffusion or through diffusion in the interface as to the time employed in the experiment (2600 hours); the time required is approximately 10,000 hours. EUTECTIC TRANSFORMATION L IN EQUILIBRIUM TO Zr6Fe23 + Fe(TAU) IN THE Fe-Zr SYSTEM [TRANSFORMACION EUTECTICA L IN EQUILIBRIUM TO ZR6FE23 + FE(TAU) EN EL SISTEMA FE-ZR]
M. S. Granovsky and D. E. Arias 1993 6 p In SPANISH Presented at the SAM 1993: 17th Metallurgical Sessions of the Argentine Metals Association; 2nd Argentine Meeting on Ceramics and Refractories, San Carlos de Bariloche, Argentina
(DE93-633766; INIS-AR-023; CONF-9304174) Avail: CASI HC A02/MF A01 (US Sales Only)

The knowledge of the phase diagram of the Fe-Zr system is important because Fe is always present as an impurity in commercial Zr-base nuclear grade alloys. This diagram has four intermetallic compounds, namely Zr3Fe, Zr2Fe, ZrFe2 and Zr6Fe23. ZrFe2 with a cubic Laves C15 structure melts congruently at 1673 deg C and Zr6Fe23 with a cubic Th6Mn23-type structure is a product of the peritectic ZrFe2 + L(r reversible)Zr6Fe23 reaction at 1482 deg C. As a part of the work on the Fe-rich portion of the system, the eutectic transformation L(r reversible)Zr6Fe23 + Fe(tau), its temperature and its composition have been studied. In order to find the eutectic temperature, sample of Zr15Fe65 and Zr4Fe96 were thermally treated at the temperature higher and lower than 1337 deg C, which was reported in the last revision of the diagram (1988). It was observed that samples treated at 1345 deg C, 1340 deg C, 1335 deg C and 1325 deg C partially melted while those treated at 1320 deg C did not. An eutectic temperature of (1325 +/- 5) deg C could be determined from the results of metallographic, X-ray and microanalysis experiments. The composition of the eutectic was determined to be (90 +/- 1) at % Fe, with the electron microprobe, by automatically averaging results on regions 10(mu)m long. DOE

IRON: WHAT IS MELT?
A. G. Duba Jun. 1993 4 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract W-7405-eng-48)
(DE94-003373; UCRL-JC-114723; CONF-930676-64) Avail: CASI HC A01/MF A01

The melting point of iron reported from a variety of phenomena observed in the laser-heated diamond-anvil-cell (DAC) and in shock wave studies differs widely. Although the three groups of investigators observing the same phenomena in the DAC are in good agreement to about 40 GPa, they disagree significantly with other measurements of melting point based on observation of different phenomena in the DAC. These latter data are in substantial agreement with some of the reported melting temperatures from two groups of investigators who measured temperature along the Hugoniot. However, a third group of investigators observe a sound velocity discontinuity along the Hugoniot and calculate a significantly lower temperature for melting. Melting point determination in iron is subject to the interpretation of physical phenomena, experimental errors which are probably larger than estimated, and perhaps undetected chemical reactions. Use of lead-indium solders in microelectronics packaging has increased over the last decade. Increased usage is due to improved properties, such as greater thermo-mechanical fatigue resistance, lower intermetallic formation rates with base metallizations (such as copper), and lower reflow temperatures. However, search of the literature reveals no comprehensive studies on phase equilibrium relations between copper metal and lead-indium solder. Our effort involves a combination of experimental data acquisition and computer modeling to obtain the Cu-In-Pb ternary phase diagram. Isotherms and isopleths of interest at low temperatures are achieved by means of differential scanning calorimetry and electron probe microanalysis.

Thermodynamic models of these sections served as a guide for efficient experimentation. DOE

The alloy CuPt is one of the few that order into a L1(sub 1) crystal structure, i.e. planes of copper and planes of planes of platinum perpendicular to the group of zone axes (111) direction. For disordered CuPt, the calculated Warren-Cowley short-range order parameter indicates an instability to concentration fluctuations with a wave-vector of ((1/2), (1/2), (1/2)), consistent with L1(sub 1) ordering. We show that this rare tendency is due to this ordering vector arising from the large joint density of states associated with L point and X point van-Hove singularities which lie near the Fermi energy. TRANSITION METALS IN HIGHLY CORRELATED DISCOTIC PHASES: DESIGNING METALLOMESOGENS WITH SELECTED INTERMOLECULAR ORGANIZATIONS Technical Report
Hanxing Zheng, Chung K. Lai, and Timothy M. Swager 8 Jan. 1994 3 p
(Contract N00014-92-J-1416)
(AD-A274695; TR-4-ONR) Avail: CASI HC A01/MF A01

The diketonate Schiff-base complexes shown below were investigated, and the square planar derivatives (M=Ni, Cu, Pd) were found to display discotic hexagonal disordered phases (Dhd). The M=VO analogs are not liquid crystalline. None of the complexes can exhibit a disc-shape independently, and in the mesophase they must organize into a superstructure which on time average leads to antiparallel alignment of nearest neighbors. These discotic antiphases exhibit a number of important properties including low melting points, low viscosity, and close intermolecular contacts of 3.6A. Additionally when put between two untreated slides, these mesophases were found to readily align with the column axes perpendicular to the surfaces. The Cu and Ni complexes exhibited very similar mesophases and lattice constants whereas the Pd complexes displayed larger intercolumnar distances and higher clearing temperatures. The differences are ascribed to greater intermolecular associations displayed by the Pd complexes. X-ray diffraction studies revealed the Ni and the Cu complexes to have an additional halo centered at approximately 7.2A which may be the result of a doubling of the period along the column axes resulting from the antiparallel arrangement of the antiphase superstructure. TOWARD INSULATING QUASICRYSTALLINE ALLOY IN Al-Pd-Re ICOSAHEDRAL PHASE
Hirofumi Akiyama, Yuko Honda, Tatsuo Hashimoto, Keiichi Edagawa, and Shin Takeuchi Apr. 1993 13 p
(ISSN 0082-4798)
(Rept-A-2666; JTN-94-80537) Avail: CASI HC A03/MF A01

The resistivities in Al70Pd20Re10 alloy of the icosahedral phase are quite sample-dependent, possibly due to slight variation of the alloy composition. In some samples, the resistivity at room temperature is approximately 0.01 omega cm and that at 4.2 K is as high as approximately 0.1 omega cm; these values are much higher than any reported values so far for quasi-crystals. The temperature dependence of the conductivity is almost linear above 4.2 K and the magnetoconductivity is negative. These dependencies are interpreted by the theory of weak localization which takes into account the spin-orbit scattering. Author (NASDA)

This report describes work during the second year of a continuing research study. The work is designed to help us understand how recombination, trapping, and band-mobility modification affecting the electronic properties of amorphous semiconductors can be measured, characterized, and described by an appropriate spectrum of defect states. We also worked to determine how light-induced defects in a Si:H and native defects in a-Si:H and native defects in a-Si:H and native defects in a SiGe:H affect transport properties in these materials. During this second year, we continued our experiments on electroluminescence (EL) and transient forward bias current, as well as photocurrent before and after light soaking. We started a program to study thin (0.4 micron) p-i-n solar cells, and we studied the effect of optical bias on charge transport in a Si:H films. We performed analytical calculations on a model that predicts an exponential energy region for band tails from dilute random charges. We developed a model for the carrier-recombination-lifetime distribution. We solved the equations for H-diffusion including deep trap levels. Lastly, we analyzed simulation data under forward bias in p-i-n devices. The most interesting and important results were obtained on the EL spectra in thin solar cell devices. We found that, at elevated temperatures, thin p-i-n devices displayed primarily defect luminescence (0.8-0.9 eV), while in thick (greater than 2 micron) devices the luminescence observed was the main band (l.l-1.2 eV). We also found that, in thin cells with buffered layers, p-b-i-n's the main band luminescence was more pronounced than that in simple p-i-n's. For the first time, we have distinguished between bulk and junction-controlled recombination. DOE

STUDY OF PRECIPITATION AND RECRYSTALLIZATION IN Al ALLOY 2519 BY BACKSCATTERED ELECTRON IMAGING METHODS M.S. Thesis
Peter J. Zohorsky Sep. 1993 64 p
(AD-A274919) Avail: CASI HC A04/MF A01

This study examines the effects of pre-strain deformation temperature, overaging temperature, and other variations in thermomechanical processing (TMP) on the mean size and size distribution of q-phase precipitate particles in Al alloy 2519. Examination was performed using the scanning electron microscope in the backscattered imaging mode, and quantitative image analysis methods were employed. The goal was to find a combination of

TMP parameters which produces q-phase particles exceeding a critical diameter for particle stimulated nucleation (PSN) of recrystallization. A necessary prerequisite for superplasticity is a uniformly fine, equiaxed grain size, and PSN is theorized to be capable of such grain refinement. Such a microstructure has been developed in aluminum alloys containing large second phase particles when the alloys are subjected to cold work and recrystallization treatments. DTIC

MICROSTRUCTURAL DEVELOPMENT IN IRRADIATED VANADIUM ALLOYS

D. S. Gelles and J. F. Stubbins (Illinois Univ., Urbana.) Sep. 1993 12 p Presented at the 6th International Conference on Fusion Reactor Materials, Stresa, Italy, 27 Sep. - 1 Oct. 1993
(Contract DE-AC06-76RL-01830)
(DE94-004307; PNL-SA-22470; CONF-930928-15) Avail: CASI HC A03/MF A01

Three simple vanadium alloys, V-5Al, V-1Ni, and V-2Ti-1Ni were examined to determine the effects of fast neutron irradiation on microstructural evolution. Specimens were irradiated in EBR II at temperatures in the range 425 to 600 C to doses of 15 and 31 dpa. Each alloy responded very differently to irradiation. All V-5Al specimens were generally void-free and contained high densities of coherent precipitates, and moderate densities of network dislocations. Swelling was much higher in V-1Ni. Voids were uniformly distributed, but with widely varying shape and size. Precipitation of two types also developed. The response in V-2Ti-1Ni was intermediate to that of the other two alloys. Irradiation produced extensive precipitation of thin rods and a moderate density of large voids often associated with much larger precipitate particles. The dislocation structure strongly interacted with the rod precipitate particles. DOE

INFLUENCE OF HELIUM GENERATION RATE AND TEMPERATURE HISTORY ON MECHANICAL PROPERTIES OF MODEL Fe-Cr-Ni ALLOYS IRRADIATED IN FFTF AT RELATIVELY LOW DISPLACEMENT RATES

M. L. Hamilton, F. A. Garner, and D. J. Edwards 1993 9 p Presented at the 6th International Conference on Fusion Reactor Materials, Stresa, Italy 1 Oct. 1993 Prepared in cooperation with Associated Western Universities, Inc., Salt Lake City, UT
(Contracts DE-AC06-76RL-01830; DE-FG06-89ER-75522)
(DE94-004264; PNL-SA-22444; CONF-930928-20) Avail: CASI HC A02/MF A01

In agreement with earlier studies conducted at higher displacement rates, evolution of mechanical properties of model Fe-Cr-Ni alloys irradiated at lower displacement rates in the Ni-59 isotopic doping experiment does not appear to be strongly affected by large differences in helium generation rate. This insensitivity to helium/dpa ratio is exhibited during both isothermal and non-isothermal irradiation. The overall behavior of the model alloys used in this study is dominated by the tendency to converge to a saturation strength level that is independent of thermomechanical starting state and helium/dpa ratio, but which is dependent on irradiation temperature and alloy composition. AN EXPERIMENTAL STUDY ON THE EFFECTS OF COMPRESSIVE STRESS ON THE FATIGUE CRACK GROWTH OF LOW-ALLOY STEEL

D. P. Jones, R. G. Hoppe, J. L. Hechmer (Babcock and Wilcox Co., Barberton, OH.), and B. A. James (Colorado School of Mines, Golden.) 1993 23 p Presented at the 1993 American Society of Mechanical Engineers (ASME) Pressure Vessel and Piping Conference, New Orleans, LA, 21-25 Jun. 1993
(Contract DE-AC11-93PN-38195)
(DE94-004447; WAPD-T-2973; CONF-9306289-1) Avail: CASI HC A03/MF A01

A series of fatigue crack growth rate tests was conducted in order to study effects of negative stress ratio on fatigue crack growth rate of low-alloy steel in air. Four-point bend specimens were used to simulate linear stress distributions typical of pressure vessel applications. This type of testing adds to knowledge on negative stress ratio effects for low-alloy steels obtained in the past from uniform tension-compression tests. Applied bending stress range was varied over twice the yield strength. Load control was used for tests for which the stress range was less than twice the yield strength and deflection control was used for the higher stress range tests. Crack geometries were both short and long fatigue cracks started at notches and tight fatigue cracks for which crack closure could occur over the full crack face. Results are presented in terms of the stress intensity factor ratio R = K(sub MIN)/K(sub MAX). The negative R-ratio test results were correlated to an equation of the form da/dN = C(Delta K/(A-R))(exp n), where A, C, and n are curve fitting parameters. It was found that effects of negative R-ratio on fatigue crack growth rates for even the high stress range tests could be bounded by correlating the above equation to only positive R-ratio test results and extending the resulting equation into the negative R-ratio regime. DOE

STRUCTURE AND PROPERTIES OF COMPOSITES SYNTHESIZED IN SITU USING SOLID STATE DISPLACEMENT REACTIONS

C. H. Henager, Jr. and J. L. Brimhall Oct. 1993 21 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contract DE-AC06-76RL-01830)
(DE94-004589; PNL-SA-21630; CONF-931009-16) Avail: CASI HC A03/MF A01

Solid state displacement reactions can produce in situ intermetallic and ceramic matrix composites in a process where an intermetallic or ceramic phase(s) and a potential reinforcing phase(s) are grown together during a solid state reaction. Interpenetrating and dispersed microstructures, important for desirable composite properties, have been produced by means of displacement reaction processing techniques. Two such composites have been synthesized which exhibit two distinct microstructures: MoSi2 reinforced with SiC particles, which exhibits a dispersed-phase structure, and NiAl/Ni3Al reinforced with Al2O3, which exhibits an interpenetrating-phase structure. Strength in bending and chevron-notch fracture toughness have been determined as a function of temperature, and measured properties compare favorably with composites produced by other means. The measured properties are discussed with regard to the observed microstructures. The potential for displacement reaction processing is assessed, and it appears to be a cost-effective synthesis method compared to others. DOE

SUPPRESSION OF THERMAL GRAIN GROWTH IN NICKEL BY PRIOR ELECTRON IRRADIATION

Yuzun Gao,, Charles W. Allen, and R. C. Birtcher Nov. 1993 7 p Presented at the Fall Meeting of the Materials Research Society, Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract W-31-109-eng-38)
(DE94-004602; ANL/MSD/CP-80133; CONF-931108-14) Avail: CASI HC A02/MF A01

An anomalous effect of electron irradiation on thermal grain growth in Ni has been observed using in situ TEM. Grain growth during thermal annealing was suppressed in areas irradiated with electrons. Grain growth suppression required a minimum electron energy between 100 and 200 keV. This alteration of thermal grain growth is attributed to electron beam injection of a surface contaminant such as carbon. This work points out that care must be exercised in the execution and evaluation of in situ TEM or ion beam experiments that deal with microstructural changes which are highly compositionally sensitive. A TRI-JUNCTION DIFFUSION COUPLE ANALYSIS OF THE Nb-Cr-Ti SYSTEM AT 950 C

D. J. Thoma and J. H. Perepezko (Wisconsin Univ., Madison.) 1993 12 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contract W-7405-eng-36)
(DE94-002637; LA-UR-93-3586; CONF-931009-10) Avail: CASI HC A03/MF A01

With a three-way diffusion couple consisting of a tri-junction between three elements, a whole spectrum of phase development and ternary equilibria is available within a single isothermal sample. Binary equilibria (for the three binary systems) are also available in single sample by analyzing diffusion zones at composition limits outside the field of ternary interaction. The tri-junction approach was employed to evaluate ternary phase formation, ternary solubility limits of binary phases, and diffusion paths in a candidate high-temperature structural system (Nb-Cr-Ti). Ternary phase equilibria and tie lines have been defined at 950 C and results confirmed with isothermal anneals of two-phase ternary alloys. The continuous solubility in TiCr2-NbCr2 region is broadened by at least 5 at. % from binary intermetallic phase fields. No new ternary phases were detected in the Nb-CrTi system at 950 C. By examining the relative shifts in the diffusion interfaces, a qualitative ranking of interdiffusion suggests that addition of Nb restricts diffusion of Cr into Ti compared to binary (Cr/Ti) behavior. CHEMICAL VAPOR DEPOSITION AND CHARACTERIZATION OF TUNGSTEN BORON ALLOY FILMS

P. M. Smith, J. G. Fleming, R. D. Lujan, E. Roherty-Osmun, J. S. Reid (California Inst. of Tech., Pasadena.), A. K. Hochberg, and D. A. Roberts 1993 8 p Presented at the Advanced Metalization for Ultralarge Scale Integration Applications in 1993, San Diego, CA, 5-10 Oct. 1993
(Contract DE-AC04-94AL-85000)
(DE94-002648; SAND-93-2445C; CONF-9310218-1) Avail: CASI HC A02/MF A01

A low pressure chemical vapor deposition (LPCVD) process for depositing W(X)B(1-X) films from WF6 and B2H6 is described. The depositions were performed in a cold wall reactor on 6 in. Si wafers at 400 C. During deposition, pressure was maintained at a fixed level in the range of 200 to 260 mTorr. Ratio of WF6/B2H6 was varied from 0.05 to 1.07. Carrier gas was either 100 sccm of Ar with a gas flow of 308 to 591 sccm, or 2000 sccm of Ar and 2000 sccm of H2 with the overall gas flow from 4213 to 4452 sccm. Two stable deposition regions were found separated by an unstable region that produced non-uniform films. The B-rich films produced in one of the stable deposition regions had W concentrations of 30 at.% and resistivities between 200 and 300 micro-ohm cm. The W-rich films produced in the other stable deposition region had W concentrations of 80 at.% and resistivities of 100 micro-ohm cm. As-deposited films had densities similar to bulk material of similar stoichiometry. Barrier properties of the films against diffusion of Cu to 700 C in vacuum were measured by four-point probe. Also, annealing was carried out to 900 C in order to determine phases formed as the films crystallize. These studies indicate that W(X)B(1-X) films may be useful barriers in ULSI metallization applications. DOE

DEFORMATION TWINNING: INFLUENCE OF STRAIN RATE

G. T. Gray, III 1993 14 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contract W-7405-eng-36)
(DE94-002693; LA-UR-93-3720; CONF-931009-9) Avail: CASI HC A03/MF A01

Twins in most crystal structures, including advanced materials such as intermetallics, form more readily as the temperature of deformation is decreased or the rate of deformation is increased. Both parameters lead to the suppression of thermally-activated dislocation processes which can result in stresses high enough to nucleate and grow deformation twins. Under high strain rate or shock-loading/impact conditions, deformation twinning is observed to be promoted even in high stacking fault energy FCC metals and alloys, composites, and ordered intermetallics which normally do not readily deform via twinning. Under such conditions and in particular under the extreme loading rates typical of shock wave deformation, the competition between slip and deformation twinning can be examined in detail. In this paper, examples of deformation twinning in the intermetallics TiAl, Ti-48Al-IV, and Ni3A as well as in the cermet Al-B4C as a function of strain rate will be presented. Discussion includes: the microstructural and experimental variables influencing twin formation in these systems and twinning topics related to high strain rate loading; the high velocity of twin formation; and the influence of deformation twinning on the constitutive response of advanced materials. THE PROCESSING OF POWDER METALLURGICALLY PRODUCED NEAR GAMMA-TITANIUM ALUMINIDE Ph.D. Thesis

Jonathan Carl Beddoes Jan. 1993 267 p
(ISBN-0-315-84018-8; CTN-94-61049) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The technology of Ti-Al intermetallics for aerospace applications is reviewed, and inherent structural and deformation characteristics are described. The relationship between microstructure and processing is examined with a focus on powder metallurgical, hot isostatic pressing (HIP), and hot deformation processes. Mechanical properties attainable with near gamma-TiAl alloys are presented and the effect of ternary elements examined. The microstructural characteristics of Ti-54 percent Al and Ti-48 percent Al-2 percent W were investigated to elucidate the microstructural evolution occurring during powder manufacture. HIP compacts exhibited a nonuniform grain size associated with a varying volume fraction of dendrite regions in the powder. Tensile ductility is related to the homogeneity of deformation between prior dendrites and interdendritic regions. The hot workability of Ti-48 percent Al-2 percent W was determined by isothermal constant strain rate forging simulations. Deformation and forgeability maps are presented for HIP material, showing the temperature strain domain at which sound forgings are produced. Combining the deformation and forgeability maps indicates that crack-free forgings are only produced by temperature/strain rate combinations at which superplastic flow contributes to the accommodation of strain. The surfaces of Immaculate 5, En58AM, and Nimonic 105 materials were studied. X ray photoelectron spectroscopy analysis was performed after cleaning using simple washing methods, and after contamination in the laboratory environment for periods of up to 156 days, using filtered and unfiltered laboratory air. The surfaces are covered by a thin oxide and this is further covered by a thin layer of carbonaceous contamination of atmospheric origin. Some of the contamination is removed by surfactants contained in various proprietary cleaners or by boiling water. The first exposure to boiling water increases the chromium content of the oxide. Exposure to the environment causes the carbonaceous contamination thickness to grow at a rate described by either the simple diffusion theory of 'logarithmic' theory such that the increase in mass of a kilogram artefact is around 15 micro-g/year after five years. If the laboratory air is filtered and moving at a low rate the carbonaceous contamination growth is low. If the filter is removed and the flow rate raised, the carbonaceous contamination rate increases. It is recommended that masses made from these materials are initially subjected to a boiling water wash for five minutes to develop a stable oxide thickness, stored in static filtered air to reduce the carbonaceous contamination, and cleaned using a dilute aqueous solution of gentle surfactant cleaners or by a steam cleaning method. THE INFLUENCE OF WELD METAL ALLOYING ADDITIONS TO EXTEND THE HEAT INPUT RANGE FOR THE SUBMERGED ARC WELDING OF HIGH STRENGTH STEELS Final Report

S. Liu, D. L. Olson, and J. E. Ramirez 16 Dec. 1993 46 p
(Contract N00014-90-J-1889)
(AD-A274284; CSM-CWR-093-015) Avail: CASI HC A03/MF A01

Weld metal microstructural development for high strength steels when welded with submerged arc welding process was investigated as a function of consumable composition and thermal experience. Of specific interest is the effect of systematic variations of microalloying additions on broadening of applicable heat input range. Controlled weld metal oxygen content, particularly in the range of 300 to 400 ppm, has been found to improve HY-130 steel weld metal toughness. Molybdenum additions was found to increase the strength of the HY-130 steel weld deposits. Copper additions up to 3.5 wt.pct. were found to strengthen the high strength steel weld metals, in particular, those of higher heat input, 3.6 kJ/mm. Niobium additions alone did not provide as powerful strengthening effect in the high heat input weld metals as the copper additions. In the case of copper-enriched welds, multi-pass welding induced both the precipitation and overaging of epsilon copper precipitates in the reheated weld metal which resulted in non-uniform mechanical properties. When added together, copper and niobium produced the synergistic effect of dual precipitation (Epsilon copper and niobium carbides) which provided the needed strength and thermal stability to the reheated weld metal even at high heat inputs. With this novel approach, the applicable heat input range to produce both adequate weld metal strength and toughness in high strength steels (Sigma y greater than 690 MPa) can be extended significantly. The optimal additions for copper and niobium were found to be 3.3 and up to 0.1 wt. pct. DTIC

ON EXPERIMENTAL STUDIES OF YIELD SURFACES OF METALS: A MORE GENERAL APPROACH

Wojciech Szczepinski and Jozef Miastkowski 1993 29 p

(ISSN 0208-5658)

(IFTR-42/1993) Avail: CASI HC A03/MF A01

In all existing experimental studies of the effect of plastic deformation on yield condition the results of tests are represented by assuming a certain standard coordinate system. When thin-walled tubular specimens are used the coordinate axes x,y are assumed to coincide with the axial and circumferential directions on the tube. When specimens are cut out from a prestressed metal sheet the coordinate axes are so chosen that they are parallel to the edges of the sheet. It is shown that the interpretation of experimental results may be more instructive if for the same test variously oriented coordinate systems x,y are used. Numerous experimental results are recalculated for variously oriented coordinate systems and then represented in the respective stress space corresponding to the assumed orientation of the reference axes. Various representations of the deformation-induced changes of the yield surface will constitute the experimental basis for a more sound analysis of the theory of deformation-induced anisotropy of metals. If the plastic properties of the tested material in its initial state are isotropic we can always choose arbitrarily a reference system in which the deformation-induced anisotropy will later be described. THE ELECTROCHEMICAL BEHAVIOR OF THE Al3Fe INTERMETALLIC COMPOUND AND LOCALIZED CORROSION OF IMPURE 1100 Al

R. G. Buchheit, L. M. Maestas, and N. R. Sorensen 1993 13 p Presented at the 183rd Electrochemical Society Meeting, Honolulu, HI, 16-21 May 1993

(Contract DE-AC04-94AL-85000)

(DE94-002037; SAND-93-1649C; CONF-930571-29) Avail: CASI HC A03/MF A01

Pitting of 1100 Al(Al-1.0(Fe,Cu,Si)) due to Al3Fe constituent particles has been studied by examining a variety of intrinsic, extrinsic, and environmental factors that contribute to localized corrosion. Consistent with results from other studies, Al3Fe is noble with respect to its microstructural surroundings and pitting is localized to the particle periphery. Polarization curves indicate that cathodic electron transfer reactions are supported on Al3Fe at high rates; however, anodic electron transfer reactions are not. Interparticle spacing appears to play a strong role in determining where pitting will occur, while Al3Fe particle area plays a lesser role. Solution pH, applied potential, and exposure time each have measurable effects on the electrochemical behavior of Al3Fe and the alpha-Al matrix phase which can impact either the galvanic potential of the Al3Fe/alpha-Al couple, or charge transfer processes on Al3Fe particles. THE ROLE OF POINT DEFECT CLUSTERS IN REACTOR PRESSURE VESSEL EMBRITTLEMENT

R. E. Stoller 1993 8 p Presented at the 6th International Symposium on Environmental Degradation of Materials in Nuclear Power Systems: Water Reactors, San Diego, CA, 3-5 Aug. 1993

(Contract DE-AC05-84OR-21400)

(DE94-001122; CONF-930825-13) Avail: CASI HC A02/MF A01

Radiation-induced point defect clusters (PDC) are a plausible source of matrix hardening in reactor pressure vessel (RPV) steels in addition to copper-rich precipitates. These PDC's can be of either interstitial or vacancy type, and could exist in either two or three dimensional shapes, e.g. small loops, voids, or stacking fault tetrahedra. Formation and evolution of PDC's are primarily determined by displacement damage rate and irradiation temperature. There is experimental evidence that size distributions of these clusters are also influenced by impurities such as copper. A theoretical model has been developed to investigate potential role of PDC's in RPV embrittlement. The model includes a detailed description of interstitial cluster population; vacancy clusters are treated in a more approximate fashion. The model has been used to examine a broad range of irradiation and material parameters. Results indicate that magnitude of hardening increment due to these clusters can be comparable to that attributed to copper precipitates. Both interstitial and vacancy type defects contribute to this hardening, with their relative importance determined by the specific irradiation conditions. DOE

SOLIDIFICATION MODELING OF A SPIRAL CASTING TO DETERMINE MATERIAL FLUIDITY

S. Ahuja, H. M. Domanus, R. C. Schmitt, L. Chuzhoy (Caterpillar Tractor Co., Peoria, IL.), and J. V. Grabel (Caterpillar Tractor Co., Peoria, IL.) 1993 11 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993

(Contract W-31-109-eng-38)

(DE94-002212; ANL/ET/CP-79010; CONF-931009-7) Avail: CASI HC A03/MF A01

In casting, fluidity is the measure of the distance a metal can flow in a channel before being stopped by solidification. During mold filling, the metal loses heat to the surrounding mold, thereby cooling and becoming more viscous until the leading portion solidifies and no further flow is possible. A coupled heat-transfer and fluid-flow modeling of a spiral, involving the use of thermophysical properties to determine material fluidity, has been conducted. Fluidity experiments were performed by Caterpillar; several spiral test castings were poured. Simulations of these experiments utilized the Casting Process Simulator (CAPS) software developed at Argonne National Laboratory. Two types of two dimensional spiral geometries with different assumptions were considered: a two dimensional laterally stretched spiral and a three dimensional lateral spiral. Computed mold filling is in good agreement with the experiment. Time required by metal/gas interface to attain specific positions in the spiral arm also compares favorably with the experiment. Influence of process variables, especially pour time, is discussed. CAPS software was used to investigate validity of dimensionality assumptions and to evaluate ability of CAPS to model fluidity adequately. DOE

POWDER SYNTHESIS, FABRICATION, AND TRANSPORT PROPERTIES OF LONG-LENGTH Ag CLAD Bi-2223 CONDUCTORS
A. N. Iyer, U. Balachandran, P. Haldar (Intermagnetics General Corp., Guilderland, NY.), J. G. Hoehn, Jr. (Intermagnetics General Corp., Guilderland, NY.), and L. R. Motowidlo (IGC/Advanced Supercomputers, Inc., Waterbury, CT.) Oct. 1993 19 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contract W-31-109-eng-38)
(DE94-002376; ANL/ET/CP-79400; CONF-931009-12) Avail: CASI HC A03/MF A01

Prereacted, polyphase powders of Pb-doped Bi-Sr-Ca-Cu-O (2223) were prepared by the solid-state reaction of appropriate amounts of Bi2O3, PbO, SrCO3, CaCO3, and CuO. The calcined powders were characterized by thermal analysis, x-ray diffraction, and scanning electron microscopy. The powders were then used to fabricate long lengths of flexible Ag-clad 2223 superconductor tapes, via the powder-in-tube technique. Growth of the 2223 phase in the tapes at each heat-treatment step has been studied. At 4.2 and 27 K improved process conditions yielded transport critical current density (J(sub c)) values greater than 10(exp 5) A/sq cm at zero field; at 77 K, J(sub c) exceeded 4 x 10(exp 4) A/sq cm. Long tapes (up to 70 m in length) have been fabricated and cowound into superconducting pancake coils and their transport properties have been characterized at 4.2, 27, 64, and 77 K. DOE

VAPOR DEPOSITION OF COPPER ON STAINLESS STEEL 304L
R. W. Vasofsky 17 Aug. 1993 9 p Presented at the Environmentally Conscious Manufacturing Congress 1993, Arlington, VA, 30 Aug. - 1 Sep. 1993
(Contract DE-AC05-84OS-21400)
(DE94-001945; Y/DZ-1032; CONF-9308150-9) Avail: CASI HC A02/MF A01

The Oak Ridge Y-12 Plant is seeking to minimize the generation of hazardous wastes in its operations. The standard procedure for electroplating a thin layer of copper on type 304L stainless steel requires several aqueous pretreatment steps which generate Resource Conservation and Recovery Act (RCRA) hazardous wastes. A more environmentally acceptable procedure was evaluated. Copper was vacuum deposited onto 304L coupons under differing deposition conditions and properties of coatings produced, including microstructure and adhesive strength, were examined. Results indicated that a noncolumnar, fine grain copper coating with high adhesion can be produced using this environmentally more acceptable approach. DOE

THE INFLUENCE OF TIG WELDING THERMAL CYCLES ON HSLA-100 STEEL PLATE Technical Report
Alan G. Fox and Sanjiwan D. Bhole Nov. 1993 22 p
(AD-A274248; NPS-ME-93-008) Avail: CASI HC A03/MF A01

A series of five bead on plate autogenous tungsten-inert-gas (TIG) welds were performed on U.S. Navy HSLA-100 steel. Power variations in these welds was achieved by altering the welding speed, voltage and current and were as follows (in kJ/mm); 0.7, 1.1, 1.2, 1.6, and 2.2. No evidence was found of either weld metal or underbead heat affected zone (HAZ) cracking in any of the welds illustrating the advantage of low carbon steel for both weld wire and base plate. Microhardness traverses across both the weld metals and HAZ's gave a maximum. Vickers diamond pyramid hardness of 345 HV in the coarse grain HAZ next to the fusion line in the lowest power weld; for the highest power weld this was somewhat lower at 328 HV. These are well below 375 which is usually considered to be the lowest Vickers Hardness value for which severe hydrogen induced cold cracking is observed in this type of steel. Optical, scanning and transmission electron microscopy studies of the coarse grain HAZ microstructure in the regions of maximum hardness was correlated with the continuous cooling transformation diagram for this steel and good agreement between observed and predicted microstructures was obtained. Shape memory alloys are a class of materials capable of producing a significant force or displacement in response to a thermal control input. Combined with their light weight, the large strains and forces available make shape memory alloys attractive for robotic applications where thermally activated devices are practical. Unfortunately, shape memory alloys are highly nonlinear, exhibiting a significant and complex hysteresis in their strain versus temperature characteristics. While models of this nonlinear characteristic have been developed, no attempt has been made to analyze the stability of a closed-loop feedback control system involving a shape memory actuator. Accordingly, the physical phenomena inherent in shape memory alloys are investigated along with their dynamic behavior. A new model for the nonlinear shape memory behavior is developed that overcomes some of the shortcomings of earlier models. Using this new model, the L2-stability of a simple position control system is proven. Experimental results are provided to confirm the model. The performance of other actuator configurations and control strategies is also examined. Author (CISTI)

THE HIGH STRAIN RATE BEHAVIOUR OF TANTALUM M.S. Thesis
Daryl G. Beckenhauer 1993 172 p
(ISBN-0-315-84472-8; CTN-94-61071) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Using a miniature direct impact Hopkinson bar, the high strain rate deformation behavior of tantalum was determined. The effects of strain rate, grain size, cold working, pre-shocking, and alloying on the flow stress of tantalum were examined. A novel method of non-contact heating was developed for the Hopkinson bar specimens. The high strain rate flow stress behavior was then determined for tantalum and Ta-10W alloy at high temperatures. True stress-strain curves from these tests were compared to results from the literature and to constitutive equations developed. These comparisons support the validity of the test results but indicate that for tantalum and tantalum alloys, variations in the degree of previous cold working and material purity are extremely important considerations when using miniature specimens. Several intermetallic compounds Al-X-Ti (x = Cu, Fe, Mn, Cr) with the L1(2) crystal structure based on Al3Ti were studied to elucidate their mechanical behavior based on various microstructural parameters. The alloys were produced by double induction melting and subsequently homogenized in vacuum. The microstructure was determined using optical and electron microscopy and x-ray diffraction. Excellent agreement was found regarding alloy composition studied with the published ternary phase diagrams. The long range order parameter S was determined for the alloys studied based on the x-ray diffraction results. Mechanical tests included harness tests, compression tests at atmospheric pressure and various temperatures (liquid N2 to 900 C) and compression tests at room temperature and hydrostatic pressures ranging from 170 to 1,000 MPa. It was found that mechanical properties depend in a systematic way on the alloy Ti content and do not depend on the atomic number of the modifying element. The S parameter inversely depends on the amount of Ti in the alloys. Ashby's ductile to brittle transition theory was applied to explain the alloy behavior. No anomaly of yield strength with temperature was found, except for Cu-modified Al3Ti. A modified Stroh's model was proposed to describe the nucleation stage of microcracks. Author (CISTI)

In the present investigation a process model has been developed to describe the quench sensitivity of AA6082 extrusions. The model is based on well-established principles of thermodynamics, kinetic theory and simple dislocation mechanics, and allows calculation of the peak hardness following artificial aging for a wide range of cooling conditions. The results show that the peak hardness is both a function of the cooling rate through the critical temperature range for Beta'-Mg2Si precipitation and the intrinsic dispersoid density in the material, in agreement with general experience. THERMOGRAVIMETRIC STUDY OF OXIDATION OF A PdCr ALLOY USED FOR HIGH-TEMPERATURE SENSORS
Darwin L. Boyd (Kent State Univ., OH.) and Mary V. Zeller Mar. 1994 10 p
(RTOP 505-62-50)
(NASA-TM-106473; E-8342; NAS 1.15:106473) Avail: CASI HC A02/MF A01

In this study, the oxidation of Pd-13 weight percent Cr, a candidate alloy for high-temperature strain gages, was investigated by thermogravimetry. Although the bulk alloy exhibits linear electrical resistivity versus temperature and stable resistivity at elevated temperatures, problems attributed to oxidation occur when this material is fabricated into strain gages. In this work, isothermal thermogravimetry (TG) was used to study the oxidation kinetics. Results indicate that the oxidation of Pd-13 weight percent Cr was approximately parabolic in time at 600 C but exhibited greater passivation from 700 to 900 C. At 1100 C, the oxidation rate again increased. Author (revised)

GRAIN BOUNDARY CHROMIUM CONCENTRATION EFFECTS ON THE IGSCC AND IASCC OF AUSTENITIC STAINLESS STEELS
S. M. Bruemmer, B. W. Arey, and L. A. Charlot Aug. 1993 17 p Presented at the 6th International Symposium on Environmental Degradation of Materials in Nuclear Power Systems: Water Reactors, San Diego, CA, 3-5 Aug. 1993
(Contract DE-AC06-76RL-01830)
(DE94-004268; PNL-SA-22941; CONF-930825-15) Avail: CASI HC A03/MF A01

Comparisons are made between grain boundary composition and intergranular stress corrosion cracking (IGSCC) of 304 and 309 austenitic stainless steels in high-temperature water environments. Chromium depletion had the dominant effect on cracking resistance with the extent of IG cracking controlled by the interfacial chromium concentration. The minimum chromium concentration required to promote cracking was a function of the applied strain rate during slow-strain-rate tensile tests in 288 C air-saturated water. Depletion from bulk levels of 18 weight percent to approximately 13.5 weight percent Cr at grain boundaries prompted 100 percent IG cracking at a strain rate of 1 x 10(exp -6)/s, while embrittlement was observed with only a slight depletion to approximately 17 weight percent at 2 x 10(exp -7)/s. Insights into critical interfacial compositions promoting IGSCC are discussed in reference to cracking of irradiated stainless steel nuclear reactor core components. DOE

CURRENT STATUS OF RESEARCH AND DEVELOPMENT ON NICKEL AND IRON ALUMINIDES
C. T. Liu, E. P. George, and C. G. McKamey 1993 13 p Presented at the 3rd International SAMPE Symposium on Intermetallics, Chiba, Japan, 7-10 Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE94-004247; CONF-931239-1) Avail: CASI HC A03/MF A01

This paper provides a comprehensive review of current status of research and development on nickel and iron aluminides based on Ni3Al, NiAl, Fe3Al and FeAl. These aluminides possess attractive properties for elevated-temperature structural use; however, brittle fracture and poor fracture resistance have limited their use as engineering materials in many cases. In recent years, considerable effort has been devoted to the study of the brittle fracture behavior of these aluminides; as a result, both intrinsic and extrinsic factors governing brittle fracture have been identified. Surprisingly, moisture-induced hydrogen embrittlement has been recognized as one of the major causes of low ductility and brittle fracture in Ni3Al, Fe3Al and FeAl at ambient temperatures. These efforts have led to the development of ductile and strong aluminide alloys for structural applications. Industrial interest in these aluminide alloys is high, and several examples of industrial involvement are mentioned. DOE

RESEARCH INTO THE MICROSTRUCTURE AND MECHANICAL BEHAVIOR OF EUTECTIC Bi-Sn AND In-Sn
J. L. F. Goldstein, Z. Mei, and J. W. Morris, Jr. Aug. 1993 11 p Presented at the 8th International Electronic Materials and Processes Congress, San Jose, CA, 30 Aug. - 2 Sep. 1993
(Contract DE-AC03-76SF-00098)
(DE94-004558; LBL-34793; CONF-9308103-1) Avail: CASI HC A03/MF A01

This manuscript reports on research into two low-melting, lead-free solder alloys: eutectic Bi-Sn and eutectic In-Sn. The microstructures were found to depend on both cooling rate and substrate, with the greatest variability in the In-Sn alloy. The nature of the intermetallic layer formed at the solder-substrate interface depends on both the solder and the substrate (Cu versus Ni). Also, the microstructure of the Bi-Sn can recrystallize during deformation, which is not the case with In-Sn. Data from creep and constant strain rate tests are given for slowly cooled samples. The creep behavior of In-Sn is constant with temperature, but the creep seems to be controlled by the In-rich phase in In-Sn on Cu and by the Sn-rich phase in In-Sn on Ni. Bi-Sn exhibits different creep behavior at temperatures above 40 C than at 20 C or lower. Stress-strain curves of Bi-Sn on Cu and In-Sn on Cu are similar, while In-Sn on Ni behaves differently. This is explained in terms of the deformation patterns in the alloys. DOE

The size and nature of precipitates have strong effects on microstructural evolution from the cold-worked state through the course of deformation at high temperatures. Through selected heat treatments and minor alloying alterations, the precipitate structure of AA5083 has been manipulated. Minor additions of Zr have been used to create fine (50 to 100 nm) precipitates. The number and size distribution of medium-sized (less than 1 micron) Mn-rich precipitates were modified by increasing the Mn concentration in conjunction with several heat treatment paths. Effects of these precipitates on the dislocation structure, recrystallization behavior, and grain growth during high-temperature deformation have been elucidated. DOE

Some of the proposed magnet case alloys for the International Thermonuclear Experimental Reactor (ITER) are metastable austenitic stainless steels. The case will be subjected to high loads and can be as much as 100 mm thick. Case assembly will probably require thick section welding with its attendant chemical inhomogeneity. Even alloys that are thermally stable with respect to martensitic transformation can, under these conditions of high stresses, cryogenic temperature, and high magnetic fields, undergo transformation. Previous work at 8 T has shown a measurable magnetic field effect on the 4.2 K tensile and fracture toughness properties of AISI300 series metastable austenitic stainless steels. Thus, it is important to understand how these alloys will behave under conditions of high magnetic fields and cryogenic temperature, particularly at the higher magnetic fields that will be used in ITER. Data at 4.2 K for 316LN indicates that the change in fracture toughness is not monotonic. It initially decreases and then later increases with applied field. DOE

(DE94-604605; CNIC-00687; SINPC-0002) Avail: CASI HC A03/MF A01 (US Sales Only)

Using the Total Absorption Method, the neutron multiplications in beryllium have been measured. A deionized water sphere with the radius of 75 cm and a polyethylene sphere with the radius of 69 cm were used as the total neutron absorbers. Neutron distributions in the spheres were measured using U-235 fission chambers. The relative and the efficiency-determined methods were compared. Important sources of experimental errors were analyzed in detail. Four groups of neutron multiplications in beryllium up to 14.85 cm thick for two total absorbers and two methods of measurement have been obtained and the agreement among them is satisfactory. Measured results have been compared with ANISN calculations. It is shown that the measured results are 3% to 14% and 1% to 7% lower than the calculations using ENDF/B-IV and ENDF/B-VI respectively. ISOTHERMAL CORROSION TESTING OF STEELS IN MOLTEN NITRATE SALTS
M. R. Prairie, S. R. Dunkin, J. M. Chavez, R. W. Bradshaw (Sandia National Labs., Livermore, CA.), and S. H. Goods (Sandia National Labs., Livermore, CA.) 1993 8 p Presented at the American Society of Mechanical Engineers (ASME) International Solar Energy Conference, San Francisco, CA, 27-30 Mar. 1994
(Contract DE-AC04-94AL-85000)
(DE94-004695; SAND-93-2334C; CONF-940326-5) Avail: CASI HC A02/MF A01

Tests were performed to evaluate the corrosivity of several nitrate salt mixtures on the containment materials likely to be used in a molten-salt solar central receiver power plant. The objective was to determine if common salt impurities (e.g., chloride) aggravate corrosion. The test was conducted for 7008 hours on A36 carbon steel at 320 C and 304 and 316 stainless steels at 570 C. Seven salt mixtures containing a variety of impurity concentrations were used. Corrosion rates were determined by descaled weight loss for coupons removed periodically from the melts. The nitrate mixtures were analyzed for changes in impurity levels and accumulation of soluble corrosion products. Test results indicate generally that corrosion is slow and that impurities do not contribute dramatically to corrosion rates of carbon and stainless steels. DOE

BENCH-SCALE SYNTHESIS OF NANOSCALE MATERIALS
M. F. Buehler, J. G. Darab, D. W. Matson, and J. C. Linehan Dec. 1993 10 p Presented at the NASA 2003 Conference, Anaheim, CA, 7 Dec. 1993
(Contract DE-AC06-76RL-01830)
(DE94-004787; PNL-SA-23284; CONF-931235-4) Avail: CASI HC A02/MF A01

A flow-through hydrothermal method used to synthesize nanoscale powders is introduced by Pacific Northwest Laboratory. The process, Rapid Thermal Decomposition of precursors in Solution (RTDS), combines high-pressure and high-temperature conditions to rapidly form nanoscale particles. The RTDS process was demonstrated on a laboratory scale and scaled up to accommodate production rates attractive to industry. The process is able to produce a wide variety of metal oxides and oxyhydroxides. The powders are characterized by scanning and transmission electron microscopic methods, surface-area measurements, and x-ray diffraction. Typical crystallite sizes are less than 20 nanometers, with BET surface areas ranging from 100 to 400 m(sup 2)/g. A description of the RTDS process is presented along with powder characterization results. In addition, data on the sintering of nanoscale ZrO2 produced by RTDS are included. DOE

AN ANODIC DISSOLUTION-BASED MECHANISM FOR THE RAPID CRACKING, PRE-EXPOSURE PHENOMENON DEMONSTRATED BY Al-Li-Cu ALLOYS
R. G. Buchheit, F. D. Wall (Virginia Univ., Charlottesville.), G. E. Stoner (Virginia Univ., Charlottesville.), and J. P. Moran (Aluminum Co. of America, Alcoa Center, PA.) 1993 17 p Presented at the Corrosion 1994: National Association of Corrosion Engineers (NACE) International Annual Conference, Baltimore, MD, 28 Feb. - 4 Mar. 1994
(Contract DE-AC04-94AL-85000)
(DE94-004798; SAND-93-1099C; CONF-940222-9) Avail: CASI HC A03/MF A01

Al-Li-Cu alloys were observed to fail in less than 24 hours after removal from a one week immersion in aerated 3.5 w/o NaCl solution. Anodic dissolution-based mechanisms proposed previously for this phenomenon were amended based on further experiment and characterization of the rapid cracking process. Amendments are based on studies of the relative electrochemical behavior of the microstructural elements in the subgrain boundary region, time to failure SCC testing in a simulated crack solution, evolution of crack potential and pH with time, fractographic examination of failed samples, and x ray diffraction of films passivating crack walls. Results suggest that an active path exists along subgrain boundaries that are comprised of the highly reactive T(sub 1) (Al2CuLi) precipitate phase and a solute depleted zone that does not readily passivate when exposed to the crack environment. The matrix phase does appear to passivate in the crack environment thereby confining the crack to the subgrain boundary region. This active path is enabled when cracks are isolated from a bulk environment, but is disabled otherwise. Potential and pH conditions required for cracking are discussed as is the formation of a hydrotalcite Li2(Al2(OH)6)2(center dot)CO3(center dot)3H2O film that appears to be responsible for passivating crack walls. PHASE STABILITY IN THE Cd-Mg SYSTEM
M. Asta, R. McCormack (California Univ., Berkeley. Lawrence Berkeley Lab.), and D. deFontaine (California Univ., Berkeley. Lawrence Berkeley Lab.) 1993 6 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contracts DE-AC04-76DR-00789; DE-AC03-76SF-00098)
(DE94-004976; SAND-94-8475C; CONF-931009-17) Avail: CASI HC A02/MF A01

Results of a theoretical study of solid-state phase equilibria and short-range order in Cd-Mg alloys are reported. Results of first-principles linear muffin-tin orbital method total-energy calculations for seven hcp-based superstructures were combined with cluster-variation-method calculations of thermodynamic properties in order to compute the Cd-Mg phase diagram. Effect on the calculated phase diagram of contributions to the alloy free energy arising from atomic vibrations and structural relaxations are assessed using available experimental information for ordered and disordered alloys in the Cd-Mg system. FRACTURE TOUGHNESS AND CRACK RESISTANCE OF DAMAGE TOLERANT AND HIGH STRENGTH Al-Li ALLOYS
R. J. H. Wanhill, L. Schra, and W. G. J. tHart 4 Jul. 1991 11 p Presented at the 6th Aluminium-Lithium Conference, Garmisch-Partenkirchen, Germany, Oct. 1991 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NLR-TP-91249-U; ETN-94-95442) Avail: CASI HC A03

Aluminum lithium (Al-Li) alloy development is motivated by prospective weight savings owing to decreased density and increased stiffness compared with conventional alloys. From an engineering viewpoint, Al-Li alloy development may be considered successful if other properties are simply maintained. Fracture toughnesses and crack resistances of several damage tolerant and high strength Al-Li sheet alloys are compared with those of the conventional 2024-T3 and 7075-T6 alloys. The practical significance for aircraft structures is discussed. ESA

STATUS AND PROSPECTS FOR ALUMINIUM-LITHIUM ALLOYS IN AIRCRAFT STRUCTURES
R. J. H. Wanhill 6 May 1992 70 p Presented at the Specialists' Conference on Fatigue of Aircraft Materials, Oct. 1992 Sponsored by Netherlands Agency for Aerospace Programs, Delft Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NLR-TP-92193-U; ETN-94-95447) Avail: CASI HC A04

The status and prospects for widespread application of Al-Li alloys in aircraft structures are examined. Particular attention is paid to the damage tolerance engineering properties of fatigue crack growth and fracture. At present the application of Al-Li alloys is very limited, because they are not direct replacements for conventional alloys and the basic material costs are usually too high. Widespread application of Al-Li alloys may well require a new generation of alloys, especially for primary structures. In the meantime, experience will be gained by selective application of the current generation of Al-Li alloys in secondary structures. ESA

A TRANSMISSION ELECTRON MICROSCOPE STUDY OF Ni4W PRECIPITATES IN A Ni-37 WT. PERCENT W ALLOY Ph.D. Thesis
Haixiong Zhao Jul. 1990 199 p
(ISBN-0-315-59932-4; CTN-94-60995) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The morphology and interfacial structure of the Ni4W body-centered phase in a Ni-W alloy were studied by transmission electron microscopy. A lath-shaped Ni4W precipitate and a multivariant domain (MVD) composite particle composed of laths of perpendicular structural variants of the Ni4W phase were observed in the Ni face centered cubic matrix. In a lath-shaped particle, a single set of shear loops was found at the (100) side plane. Sets of interfacial ledges, lying parallel to the lath axis and with different 011-type Burgers vectors, were identified at the habit plane. At the MVD/matrix interface, which corresponded to the (100) plane of the laths, screw dislocations as well as strong diffraction contrast oscillation were observed. Two sets of shear loops lying in the (0,-1,1) perpendicular twin boundaries of the MVD with alternating anti-parallel Burgers vectors in the 011 direction were observed. These accommodate the alternating shear strain resulting from the alternating arrangement of perpendicular twins in the MVD. The displacement field associated with such screw dislocation arrays was evaluated. The results indicate that the minimization and accommodation of the transformation strain determined both the morphology and related interface structure of the Ni4W phase. Author (CISTI)

CREEP RUPTURE PROPERTIES OF A NICKEL-BASE HEAT-RESISTANT ALLOY HASTELLOY XR UNDER VARYING TEMPERATURE/STRESS CONDITION
Hirokazu Tsuji (Japan Atomic Energy Research Inst., Tokai.), Hajime Nakajima (Japan Atomic Energy Research Inst., Tokai.), Tatsuhiko Tanabe, and Yuji Nakasone May 1993 29 p In JAPANESE Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-701175; JAERI-M-93-105) Avail: CASI HC A03 (US Sales Only)

A series of constant temperature and load creep rupture tests and varying temperature and/or load creep rupture tests was carried out on a nickel-base heat-resistant alloy Hastelloy XR, which was developed for applications in the High-Temperature Engineering Test Reactor, at 850 to 1000 C in the simulated HTGR helium gas. This report describes the applicability of the conventional creep damage rules, i.e., the life fraction, the strain fraction and their mixed rules, to the alloy. The applicability was examined using the data under varying both temperature and load conditions as well as those, which were obtained in the previous work, under constant temperature and varying load conditions. The life fraction rule showed the best applicability of these three criteria. The good applicability of the rule was considered to show that the change of the chemical composition and/or the microstructure during exposure to the high-temperature simulated HTGR helium environment was not appreciable to affect the creep strength of Hastelloy XR. Though the life fraction rule under varying both temperature and load conditions is slightly less applicable than that under constant temperature and varying load conditions, it has been concluded that the rule is applicable in engineering design of high-temperature components made of Hastelloy XR. HYDROTHERMAL GROWTH AND CHARACTERIZATION OF OXIDES IN ZIRCONIUM ALLOYS
M. Villegas, A. M. Olmedo, R. A. A. Bordoni, M. A. Blesa, G. Rigotti, and A. J. G. Maroto 1993 2 p Presented at the 8th Argentine Congress on Physico-Chemistry, Mar del Plata, Argentina, 19-22 Apr. 1993
(DE94-602981; INIS-AR-039; CONF-9304214) Avail: CASI HC A01/MF A01 (US Sales Only)

The morphological and microstructural characterization of hydrothermally grown oxides is required to predict long term alloy corrosion behavior. Gere, two Zirconium alloys are compared: Zry-4 and Zr-2.5% Nb, both used for fuel elements and in-core structural components in water cooled nuclear reactors. Long term experiments were performed in autoclaves without recirculation, with high pressure steam at 435 C, and in on-line autoclaves in Embalse Nuclear Power Plant, under primary circuit chemistry. The oxides were characterized at different growth stages. The possible growth mechanisms are discussed. Derived from text

EFFECT OF DIFFERENT IONS ON THE ANODIC BEHAVIOUR OF ALLOY 800 IN CHLORIDE SOLUTIONS AT HIGH TEMPERATURE
C. J. Lafont and M. G. Alvarez 1993 3 p Presented at the SAM 1993: 17th Metallurgical Sessions of the Argentine Metals Association; 2nd Argentine Meeting on Ceramics and Refractories, San Carlos de Bariloche, Argentina, 13-16 Apr. 1993
(DE94-602982; INIS-AR-042; CONF-9304174) Avail: CASI HC A01/MF A01 (US Sales Only)

The anodic behavior and passivity breakdown of alloy 800 in sodium bicarbonate and sodium phosphate aqueous solutions was studied in the temperature range from 100 C to 280 C by means of electrochemical techniques. The effect of phosphate or bicarbonate additions on the pitting susceptibility and pitting morphology of the alloy in chloride solutions was also examined. The composition of the tested material was: 19.55% Cr; 30.80% Ni; 0.064% C; 0.75% Mn; 0.37% Si; 0.29% Ti; 0.09% Cu; 0.002% S; 0.013% P; 0.27% Al; 0.07% Co; bal. Fe. The results showed that the presence of bicarbonate or phosphate ions increases the pitting potential of alloy 800 in chloride solutions. Changes in pitting morphology were found in phosphate containing solutions, while the pits found in bicarbonate containing solutions were similar to those formed in pure chloride solutions. DOE

ION-DRIVEN PERMEATION OF DEUTERIUM IN METALS
Wei-Min Shu (Kyushu Univ., Fukuoka, Japan.), Yasunori Hayashi (Kyushu Univ., Fukuoka, Japan.), and Kenji Okuno (Japan Atomic Energy Research Inst., Naka.) Mar. 1993 68 p
(DE94-701104; JAERI-M-93-043) Avail: CASI HC A04/MF A01

A general model of ion-driven permeation of hydrogen isotopes at steady state is presented. In this model, new transport parameters, which not only have clear physical meanings but also contain the implanted range, are developed to distinguish the regime of ion-driven permeation at steady state. The model shows that the transport regime of ion-driven permeation depends on the incident ion flux, the thickness of membrane, the implanted range, diffusion coefficients, and recombination coefficients on both sides of the membrane. The permeation behavior of deuterium implanted into pure iron, Fe-Ti alloys, and pure molybdenum are investigated. The permeation spike, permeation regime, and the effect of the incident ion energy on permeation rate are discussed. DOE

THE TRANSITION FROM STRESS CORROSION CRACKING TO CORROSION FATIGUE IN AA-7075 AND AA-8090 Ph.D. Thesis
Johann Rechberger Sep. 1989 214 p
(ISBN-0-315-59526-4; CTN-94-61005) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The transition between stress corrosion cracking (SCC) and corrosion fatigue (CF) was investigated in two high-strength aluminum alloys, the well established Al-Zn-Mg-Cu alloy AA-7075 and the new generation Al-Li-Cu-Mg alloy 8090. The effect of crack tip strain rate (CTSR) on environmentally assisted cracking was studied in the artificially aged condition using fatigue precracked double cantilever beam specimens, with the crack plane parallel to the rolling plane, under monotonic and cyclic loading. At low K-rates (average change in stress intensity over time), real-time crack velocities under monotonic slow or constant load conditions were comparable to crack velocities obtained with cyclic loading experiments. As K-rate increased, real-time crack velocities decreased due to plasticity induced crack growth retardation effects and decrease in crack tip film rupture. With alloy 7075, a crack tunnelling mechanism was found to overcome this crack growth retardation. Alloy 8090 exhibited high resistance to SCC. It is concluded that transition from intergranular SCC to intergranular CF occurs at a critical K-rate. Below this rate, crack velocities are not increased by cyclic loading; instead, crack growth retardation effects can result in lower real-time crack velocities than those typical for constant load tests at comparable stress intensities but much lower K-rates. LOW STRAIN BEHAVIOUR OF A PARTICULATE REINFORCED ALUMINUM ALLOY Ph.D. Thesis
Stephen Corbin 1992 292 p
(ISBN-0-315-84906-1; CTN-94-61107) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

An investigation was conducted on the strengthening that arises when an Al alloy is reinforced with approximately equiaxial SiC particles. The results indicate that most of the strengthening derived from the particles develops at low strains, mainly due to the high strain hardening rate during onset of plastic flow. Examination of the Bauschinger effect in the composites indicates that an internal stress develops rapidly in the low strain regime. Microstructural observations suggest that the nature of this flow is influenced by the SiC particle distribution. Initial plasticity appears to be associated with relatively particle-free regions of the microstructure. A self consistent model is developed for calculating the stress partitioning that occurs between the Al matrix and the SiC particles during the elastic/plastic transition and beyond. Excellent quantitative agreement between the experimentally measured elastic modulus and the model prediction was achieved. The influence of particle distribution was examined by representing the composite microstructure as a bimodal mixture consisting of a particle-rich and a particle-free phase. Like the self consistent model, this model also predicts an increase in the initial strain hardening rate. Unlike in the other model, the magnitude of that rate is comparable to experimental measurements. Author (CISTI)

STRUCTURAL STUDY OF Cu/Co MULTILAYER BY ANOMALOUS SMALL-ANGLE X RAY SCATTERING c76
Eiichiro Matsubara and Yoshio Waseda *In its* The Science Reports of the Research Institutes, Tohoku University. Series A: Physics, Chemistry, and Metallurgy. Volume 38, No. 1: Amorphous Materials 14 29 Mar. 1993 p 14-23 (For primary document see N94-28158 07-26)
Avail: CASI HC A02/MF A02

The diffraction peaks in the small-angle region due to a long period of a Cu/Co multilayer were observed with the anomalous small-angle X-ray scattering in reflection geometry. These peaks appear to be enhanced because of a large negative value of the real part of the anomalous dispersion term of Co just below the Co K-absorption edge. By comparing the relative integrated intensities of these peaks with the theoretical values calculated from a trapezoidal concentration model, the concentration profile along the surface normal in this multilayer has been determined. Avail: CASI HC A02/MF A02

The processes of Solid State Amorphization (SSA) and subsequent crystallization in Zr/Co and Zr/Ni multilayered thin films have been studied by Differential Scanning Calorimetry (DSC). The thermodynamic values, i.e., the enthalpy change delta H(sub a) and the activation energy E(sub a) for amorphization as well as the enthalpy change delta H(sub x) and the activation energy E(sub x) for crystallization, were evaluated from the DSC experiments. These values were compared with those of the corresponding rapidly quenched amorphous alloys. The activation energies E(sub a), calculated by the modified Ozawa method, are 150 and 132 kJmol(exp -1) for Zr/Co and Zr/Ni multilayers respectively. These values are equivalent to the previously reported activation energy of diffusion of Co or Ni in the rapidly quenched amorphous Zr-Co or Zr-Ni alloys. Author (NASDA)

NMR STUDY OF QUASICRYSTAL Al(70)Pd(20)T(M10) ALLOY (T(M):Cr, Mn, Fe, AND Co) **c76**
Takeshi Shinohara and Takashi Sato *In its* The Science Reports of the Research Institutes, Tohoku University. Series A: Physics, Chemistry, and Metallurgy. Volume 38, No. 1: Amorphous Materials 14 29 Mar. 1993 p 34-42 (For primary document see N94-28158 07-26)
Avail: CASI HC A02/MF A02

Nuclear Magnetic Resonance (Al-27, Mn-55, and Co-59) measurements have been made on quasicrystalline phases of the Al70Pd20T(sub M)10 alloy (T(sub M): Cr, Mn, Fe and Co) in the temperature range between 5 K and room temperature. There is no marked temperature dependence in peak shift and line width of either the Al-27 or Co-59 NMR spectra, except for the Al-27 and Mn-55 spectra in the Al70Pd20Mn10. However, the peak shift of these spectra depends upon the constituent transition element. For the Al70Pd20Mn10, the negative Al-27 Knight shift and line broadening at low temperatures indicate that there exist two classes of Mn atoms, magnetic and nonmagnetic ones. Author (NASDA)

FORMATION AND CRYSTALLIZATION OF HYDROGEN-INDUCED AMORPHOUS Ti3InH(4.5) ALLOY **c76**
Katsuhiko Mori, Kiyoshi Aoki, and Tsuyoshi Masumoto *In its* The Science Reports of the Research Institutes, Tohoku University. Series A: Physics, Chemistry, and Metallurgy. Volume 38, No. 1: Amorphous Materials 14 29 Mar. 1993 p 43-52 (For primary document see N94-28158 07-26)
Avail: CASI HC A02/MF A02

Structural changes of a titanium compound Ti3In with the D0(19) structure caused by hydrogenation have been investigated by X-Ray Diffraction (XRD) and transmission electron microscopy. Crystallization and hydrogen desorption behavior of the hydrogen-induced amorphous alloy have been studied by differential scanning calorimetry, XRD, and hydrogen analysis. On hydrogenation of the Ti3In compound, an amorphous single phase a-Ti3InH(4.5) is formed below about 350 K where the c-Ti3InHx phase having the bcc (body centered cubic) structure is formed. Hydrogen absorption of Ti3In occurs between 32 and 36 ks drastically which gives rise to non-solid solution type amorphization at 300 K. The a-Ti3InH(4.5) crystallizes to fcc (face centered cubic) type c-Ti3InH(4.5) above 484 K. Hydrogen is desorbed from the crystalline phase above the crystallization temperature. Author (NASDA)

THE CORROSION BEHAVIOR OF SPUTTER-DEPOSITED MAGNESIUM-VALVE METAL ALLOYS
Eiichi Hirota, Hiroki Habazaki, Asahi Kawashima, Katsuhiko Asami, and Koji Hashimoto *In its* The Science Reports of the Research Institutes, Tohoku University. Series A: Physics, Chemistry, and Metallurgy. Volume 38, No. 1: Amorphous Materials 14 29 Mar. 1993 p 53-62 (For primary document see N94-28158 07-26)
Avail: CASI HC A02/MF A02

An attempt was made for preparation of magnesium alloys with valve metals, such as titanium, zirconium, niobium, and tantalum whose melting point far exceed the boiling point of magnesium. These alloys became single phase solid solutions in wide composition ranges but were crystalline in contrast to the fact that other alloys with valve metals such as nickel-, copper-, and aluminum-base alloys were amorphous in wide composition ranges. The alloys containing sufficient amounts of valve metals showed high corrosion resistance due to spontaneous passivation in 1 M HCl at 30 C. The high corrosion resistance was attributed to the formation of passive oxyhydroxide films in which valve metal cations were remarkably concentrated. However, because of crystalline alloys and because of the presence of active magnesium, their corrosion resistance is lower than that of valve metals. Author (NASDA)

Avail: CASI HC A03/MF A02

Exploratory work has been done on the performance of electrocatalytic reduction of oxygen and anodic oxidation of ethylene and methane on the gas-diffusion electrodes prepared from amorphous alloys containing one atomic percent platinum group elements. Gas-diffusion electrodes were made by coating the mixture of catalysts prepared by immersion in 46 percent HF from melt-spun ribbon shaped amorphous alloys, carbon black, poly tetra fluoro ethylene and sugar, and subsequent baking in nitrogen gas. The electrode made of catalyst prepared from amorphous nickel-niobium alloy containing platinum and ruthenium was the most active for electrocatalytic reduction of oxygen. For electro-oxidation of ethylene and methane, amorphous nickel-valve metal alloy containing only platinum possesses higher activity in comparison to the electrode made of platinum black powder. CO2 METHANATION CATALYSTS PREPARED FROM AMORPHOUS NI-VALVE METAL ALLOYS CONTAINING PLATINUM GROUP ELEMENTS
Kenichiro Wakuda, Hiroki Habazaki, Asahi Kawashima, Katsuhiko Asami, and Koji Hashimoto *In its* The Science Reports of the Research Institutes, Tohoku University. Series A: Physics, Chemistry, and Metallurgy. Volume 38, No. 1: Amorphous Materials 14 29 Mar. 1993 p 76-87 (For primary document see N94-28158 07-26)
Avail: CASI HC A03/MF A02

The amorphous Ni-valve metal (Ti, Zr, Nb, and Ta) alloys containing a few at percent of platinum group elements were activated by immersion into hydrofluoric acid and used for hydrogenation of carbon dioxide at 100 to 300 C. This surface activation led to formation of nanocrystalline surface alloys with high surface area, and to surface enrichment of platinum group elements on the titanium, niobium, and tantalum-containing alloys, but not on the zirconium-containing alloys. The surface of the latter alloys was mainly composed of nickel. The activity and selectivity for methane formation on the titanium, niobium, and tantalum-containing alloys were significantly affected by the difference in the platinum group elements; the ruthenium and rhodium-containing alloys showed higher activity and selectivity for methane formation while the platinum-containing alloys exhibited the lowest activity for methane formation and produced mainly carbon monoxide. The zirconium-containing alloys showed the one order of magnitude higher activity for methanation of carbon dioxide in comparison with the titanium, niobium, and tantalum-containing alloys and produced exclusively methane independent of platinum group elements contained. The alloying with zirconium seems very important to prepare the alloy catalysts having the extremely high activity. Author (NASDA)

MECHANICAL BEHAVIOR OF AMORPHOUS ALLOYS AT ELEVATED TEMPERATURES
Hiroshi Okumura, Akihisa Inoue, and Tsuyoshi Masumoto *In its* The Science Reports of the Research Institutes, Tohoku University. Series A: Physics, Chemistry, and Metallurgy. Volume 38, No. 1: Amorphous Materials 14 29 Mar. 1993 p 88-98 (For primary document see N94-28158 07-26)
Avail: CASI HC A03/MF A02

Mechanical behavior of amorphous alloys has been investigated through the static and dynamic mechanical measurements. Two stress relaxation systems are observed in the dynamic measurements; the sub-T(sub g) relaxation and the T(sub g) relaxation. These relaxations seem to cause the change in the deformation mode from inhomogeneous to homogeneous deformation which is seen in the static stress-strain curves. The stress relaxation systems also correlate to the ductility of amorphous alloys. The decrease in the stress relaxation resulting from the lack of the sub-T(sub g) relaxation causes embrittlement. FORMATION OF GLASSY Pd-Ni-P ALLOYS BY MECHANICAL ALLOYING AND THEIR STRUCTURE AND THERMAL STABILITY
Akihisa Inoue, Kensuke Matsuki, and Tsuyoshi Masumoto *In its* The Science Reports of the Research Institutes, Tohoku University. Series A: Physics, Chemistry, and Metallurgy. Volume 38, No. 1: Amorphous Materials 14 29 Mar. 1993 p 99-111 (For primary document see N94-28158 07-26)
Avail: CASI HC A03/MF A02

This report reviews the recent research on whether or not the application of mechanical alloying to metallic alloys causes a glassy structure defined by the distinct appearance of glass transition and supercooled liquid region before crystallization. The amorphous phase in Pd48Ni32P20 alloy produced by mechanical alloying of a pre-alloyed ingot consisting of Pd5P2 and Ni3P phases was found to exhibit distinct glass transition, followed by the appearance of a wide supercooled liquid region and then crystallization. Based on these data, it has been concluded that the mechanical alloying method is useful for the formation of glassy metallic materials, in addition to the preparation of amorphous materials without glass transition and nonequilibrium crystalline phases. STUDY ON THE PRODUCTION OF FLAKY AMORPHOUS ALLOY POWDERS BY IMPACT FLATTENING OF ATOMIZED LIQUID DROPLETS ON A RAPIDLY ROTATING WHEEL
Akihisa Inoue, Masahiro Oguchi (Teikoku Piston Ring Co. Ltd., Okaya, Japan.), and Tsuyoshi Masumoto *In its* The Science Reports of the Research Institutes, Tohoku University. Series A: Physics, Chemistry, and Metallurgy. Volume 38, No. 1: Amorphous Materials 14 29 Mar. 1993 p 112-128 (For primary document see N94-28158 07-26)
Avail: CASI HC A03/MF A02

A two-stage quenching technique consisting of impact flattening of atomized supercooled liquid droplets caused the production of flaky amorphous powders with a thickness of 1 to 3 micrometers and an aspect ratio of 20 to 300 in Co-, Fe-, and Al-based systems. The flaky powders consist of an amorphous phase over the entire particle size range even in the alloy systems where no amorphous phase is formed in the particle size below 25 micrometers by high-pressure gas atomization. The improvement of the production ratio of the amorphous powders is due to the following three factors: the second-stage cooling of supercooled liquid droplets, the reduction of powder thickness to 1 to 3 micrometers, and the high thermal conductive stage between rotator and powder resulting from the high-energy collision. The flaky powders also have a smooth surface and edge combined with a uniform thickness, leading to good luster, high reflection ratio against light, high corrosion resistance, high mechanical strength, and anisotropic magnetic properties. Furthermore, the unique morphology causes a high laminating tendency in a resin. By utilizing these advantages, the flaky amorphous powders are expected to be used as magnetic filler and corrosion-resistant coating materials. Author (NASDA)

PRODUCTION OF AN AMORPHOUS Fe(75)Si(10)B(15) SHEET BY A METALLIC MOLD CASTING METHOD AND ITS PROPERTIES
Akihisa Inoue, Hirokazu Yamamoto (Unikita Ltd., Uji, japan.), Takanobu Saito (Daido Steel Co. Ltd., Nagoya, Japan.), and Tsuyoshi Masumoto *In its* The Science Reports of the Research Institutes, Tohoku University. Series A: Physics, Chemistry, and Metallurgy. Volume 38, No. 1: Amorphous Materials 14 29 Mar. 1993 p 129-137 (For primary document see N94-28158 07-26)
Avail: CASI HC A02/MF A02

The application of a metallic mold casting method to an Fe75Si10B15 alloy with the largest glass-forming ability in (Fe, Co, Ni) -Si-B system was found to cause the formation of a mostly single amorphous phase in a sheet form with a thickness of 0.1 mm. No distinct difference in thermal stability (crystallization temperature and heat of crystallization), hardness, Curie temperature, and magnetization is detected between the as-cast sheet and the melt-spun amorphous ribbon with a thickness of 0.02 mm. On the other hand, bending ductility, heat of relaxation, delta H(sub r), and coercivity, H(sub c), which can be regarded as structure sensitive properties, are significantly different from those for the amorphous ribbon. That is, the sheet sample fractures during bending deformation and has a smaller delta H(sub r) and a larger H(sub c). The difference is induced presumably because the sheet sample has a more relaxed atomic configuration on a short-range scale as compared with that for the amorphous ribbon sample. Author (NASDA)

FORMATION AND HIGH MECHANICAL STRENGTH OF Al-BASED ALLOYS CONTAINING A NANOSCALE ICOSAHEDRAL PHASE AS A MAIN CONSTITUENT
Akihisa Inoue, Mitsuru Watanabe (Akita Univ., Japan.), Hisamichi Kimura, and Tsuyoshi Masumoto *In its* The Science Reports of the Research Institutes, Tohoku University. Series A: Physics, Chemistry, and Metallurgy. Volume 38, No. 1: Amorphous Materials 14 29 Mar. 1993 p 138-160 (For primary document see N94-28158 07-26)
Avail: CASI HC A03/MF A02

This report reviews recent results on the achievement of high tensile strength and good ductility for rapidly solidified Al-Mn-Ln and Al-Cr-Ln (Ln = lanthanide metal) alloys containing an icosahedral phase as a main constituent phase. The good mechanical properties are attributed to the simultaneous achievement of the following three structural effects resulting from rapid solidification and appropriate alloy design: the formation of a mixed structure consisting of nanoscale icosahedral particles surrounded by Al phase; the formation of the icosahedral phase at low solute concentrations; and the achievement of an ultra-fine mixed state of icosahedral and approximant regions caused by the phase strain-induced approximant transition in the nanoscale icosahedral particles. The utilization of the structural effects is expected to cause high mechanical strengths combined with good ductility for other quasicrystalline alloys. Author (NASDA)

PHOTOELECTRON SPECTROSCOPIC STUDIES OF THE ELECTRONIC STRUCTURE AND BONDING IN TiC AND TiN
S. V. Didziulis, J. R. Lince, T. B. Stewart, and E. Eklund (International Business Machines Corp., Armonk, NY.) 30 Sep. 1993 41 p
(Contract F04701-88-C-0089)
(ATR-93(8361)-2) Avail: CASI HC A03/MF A01

Titanium carbide (TiC) and nitride (TiN) possess remarkable physical properties, such as extremely high hardness and melting point, that promote their use as anti-wear materials under harsh tribological conditions. These physical properties must arise from chemical bonding phenomena that result from the inclusion of the non-metal atom within the metallic matrix, and these bonding phenomena should be apparent in measurements of the valence-band electronic structures TiC and TiN. The surface electronic structure and bonding in TiC(100) and TiN (110) with core and valence level photoelectron spectroscopies (PES) using x rays (1486.6 eV) and synchrotron radiation in the range of 28 to 180 eV were explored. Intensity changes in the valence-band features are followed as a function of incident photon energy; these changes are then compared to theoretical atomic photoionization cross sections to determine the atomic origins of these features. Resonant PES at the Ti 3p absorption edge is used to determine titanium 3d contributions to the valence band and to show differences in the electronic structures in TiC and TiN. A new resonance phenomenon near the Ti 3s edge in TiC was observed, and its possible assignment is discussed. The electronic structure and bonding in these materials is well described by molecular orbital theory, where the Ti and non-metal ions in their formal oxidation states (e.g., Ti(4+) and C(4-) in TiC) undergo covalent bonding interactions. Overall, the PES results indicate greater covalent mixing for TiC as compared to TiN, consistent with the differences in the electronegativities of the atoms. Specifically, stronger covalent interactions between the C 2s, 2p and the Ti 3d, 4s, and 4p levels must occur to explain the spectroscopic differences between TiC and TiN. In addition, there is no evidence for an occupied TiC valence level having predominantly Ti character (unlike TiN), precluding the existence of direct Ti-Ti bonding in TiC. Any such orbital overlap is significantly affected by the carbon atoms in the lattice. Author (revised)

MECHANICAL PROPERTIES AND MICROSTRUCTURE OF THERMOMECHANICALLY PROCESSED, HIGH MANGANESE STEEL Final Report
J. F. Chinella Aug. 1993 16 p Repr. from High Manganese, High Nitrogen Austenitic Steels (Metals Park, OH, ASM International) 1993 p 143-153
(ARL-TR-146) Avail: CASI HC A03/MF A01

Thermomechanical treatments (TMT's) were performed on an austenitic Fe-12.5Mn-2.0Mo-1.15C Hadfield steel to achieve a material with high strength and resistance to plastic instability. Mechanical properties were evaluated by tensile deformation; microstructures and deformation modes were evaluated by optical or electron microscopy. Solution treated 16-18 Rockwell C hardness (HRC) material was warm rolled to a hardness of 39-53 HRC. During tensile deformation, strain hardening occurred with increasing loads and high uniform elongations to ultimate strengths equivalent to 56-57 HRC. Microstructures and deformation modes resemble those attributed to austenitic steels and other face centered cubic alloys with low to moderate stacking fault energy. Deformation was localized within grains in a orientation dependent crystallographic manner, often concentrated within bands consisting of slip and twinning. Substructures and microcracks were often restrained to grain size scale. Author (revised)

HIGH QUALITY ALUMINIUM CASTINGS CONFERENCE
J. Poranen, ed. and J. J. Vuorinen, ed. 1993 225 p Conference held in Otaniemi, Finland on May 13-14, 1993
(PB94-133592; ISBN-951-22-1638-8) Avail: CASI HC A10/MF A03

The importance of the theme of the conference, high quality aluminum castings, is quite obvious. Firstly, aluminum is the most common metal in the world. Its crustal abundance is eight percent. Secondly, the pressure to reduce the mass of machine parts is becoming higher and higher. Aluminum, owing to its specific density of only one third of that of steel, is self-evidently one of the most interesting materials in aiming at mass reductions. Thirdly, there are severe quality problems in aluminum castings, especially in those made of secondary aluminum. Finland is a country with no primary aluminum production, and therefore secondary aluminum is a more important raw material than primary aluminum in Finland. NTIS

DYNAMIC RESPONSE OF S-2 GLASS REINFORCED PLASTIC STRUCTURAL ARMOR
Shun-Chin Chou and Eugenio DeLuca Dec. 1993 120 p
(AD-A273868; ARL-SR-5) Avail: CASI HC A06/MF A02

A progress report on work conducted in FY93 to define the dynamic response of S-2 glass reinforced plastic laminate under ballistic loading is presented. The work is divided into three parts, a description of ballistic impact damage in monolithic laminates produced by fragment simulators and measurement of target residual compressive strength, determination of material dynamic properties, and measurement and analysis of stress levels in glass reinforced plastic laminates under ballistic impact. Enlargement and extension of the data base constructed is planned for FY94. The overall objectives of this effort are to provide design guidelines for application of S-2 glass reinforced plastic in vehicular structures and to define the dynamic behavior of this material for general applications in armor technology. HIGH IMPACT STRENGTH POLY(LACTIDE) TOUGH BIODEGRADABLE MATERIALS Ph.D. Thesis
Dirk Wybe Grijpma 1993 179 p Sponsored by Stichting Biomat, Netherlands Prepared in cooperation with DSM/NV Nederlandse Staatsmijnen, Geelen, Netherlands, and Ministere van Economische Zaken, s'Gravenhage, Netherlands
(ETN-94-95389) Avail: CASI HC A09/MF A02

Research on poly(lactide) aimed at gaining more insight into the factors which determine the physical properties and the applicability of these degradable polymers in biomedical devices is described. An important aspect is the preparation of strong and tough amorphous materials, which are able to degrade in the human body by hydrolysis to harmless compounds. These materials are primarily designed for use as bone plates and screws in maxillofacial surgery, but many other uses in medicine and in other fields are conceivable. Materials based on L-lactide were prepared by copolymerization with several other cyclic esters, by blending amorphous poly(lactide) polymers with degradable rubbers and by synthesizing (star)block copolymers containing poly(lactide) sequences. Fundamental problems relating the poly(lactide) chain stiffness and configuration in the melt to the observed fracture behavior are addressed, as well as more practical problems such as the influence of processing variables on the properties of poly(lactide). NNN-ISING MODEL SIMULATION OF NANODOMAIN TEXTURES IN RELAXOR-TYPE LEAD SCANDIUM TANTALATE
H. Qian, J. L. Peng, and L. A. Bursill 1993 21 p
(DE94-601884; UM-P-93/23) Avail: CASI HC A03/MF A01 (US Sales Only)

Chemical domain textures for lead scandium tantalate (PST) are modelled using Monte Carlo (MCS) and next-nearest-neighbour Ising (NNNI) models. A wide range of degrees of short- and long-range ordering of the (Ta,Sc) atoms occur in ceramic specimens, depending on processing routes. The simulations help to understand and quantify the chemical domain textures, chemical domain wall configurations and other chemical defects which may occur in certain relaxor-type perovskite-type oxides. The results are compared to dark-field transmission electron microscopic observations. Some new types of small defects were discovered. These are described and classified. The results provide a first step towards the development of a microscopic statistical physics framework for analytical theories of the dielectric response of relaxor-type ceramics, where the frequency and temperature variation of the permittivity are due essentially to dipolar-type fluctuations on nanometer scales. CRYSTALLIZATION AND MICROSTRUCTURAL CONTROL OF FERROELECTRIC THIN-FILMS AND GLASS-CERAMICS Interim Report, 1 Mar. 1992 - 30 Sep. 1993
Michael J. Haun 30 Sep. 1993 111 p
(Contract N00014-92-J-1390)
(AD-A273767) Avail: CASI HC A06/MF A02

Research on solution-derived ferroelectric thin films and melt derived ferroelectric glass ceramics is being conducted in parallel with considerable overlap in the compositions studied and the evaluations of the crystallization behavior, microstructural development, and resulting properties. By establishing the similarities and differences between the two systems, techniques developed for one technology can then be applied to advance the other. The investigation is focusing on the Pb(Zr(x)Ti(1-x))O3-Pb5Ge3O11 (PZTPG) system. Compositions from this system combine the glass forming ability and low processing temperatures of PG with the excellent electrical properties of PZT. These compositions crystallize into multiple ferroelectric phases, and thus by controlling the ratios of these phases unique combinations of properties may be possible. The high PG compositions are being investigated for pyroelectric applications, while the high PZT compositions are of interest for piezoelectric applications. This program investigates melt-derived PG-PZT compositions, the crystallization of multiple ferroelectric phases, and the crystallization of PZT from a glass. This research demonstrates the feasibility of developing piezoelectric glass-ceramics with low processing temperatures that utilize powder processing techniques, such as pressing, screen printing, or tape casting, and indicates the potential of incorporation of these materials into low-fired multilayer packages as a sensors or actuators. TECHNIQUE TO PREDICT THE CURING BEHAVIOUR OF UNSATURATED POLYESTER MATERIALS
P. A. J. Gibbs and M. Rides 1993 22 p See also PB94-124864
(PB94-124856; DMM(A)-120) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The curing behavior of a thermosetting unsaturated polyester dough molding compound (DMC) has been investigated using differential scanning calorimetry (DSC). The cure reaction was found to have two separate distinct regions: an inhibition period where the material was prevented from curing by the action added inhibitors with little or no change occurring in the rheological behavior of the material, and a cure region where the DMC hardens to produce the final cured article. A kinetic model has been developed for polyester DMC's using a kinetic model containing two rate constants derived from DSC measurements. The model obtained has been used to estimate fill times and in-mold hardening times during processing. Good agreement has been obtained between molding practice and the kinetic model indicating that a good model has been obtained. NTIS

MODELLING THE INHIBITION CURE BEHAVIOUR OF UNSATURATED POLYESTER MOULDING MATERIALS
P. A. J. Gibbs and N. Rides 1993 22 p See also PB94-124856
(PB94-124864; DMM(A)-107) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

Much work has been carried out on measuring the curing behavior of unsaturated polyester molding compounds. However, previous modeling work has usually ignored the effect that cure-preventing inhibitors have of the curing behavior of the material. An analysis method has been developed for determining the inhibition behavior of an unsaturated polyester dough molding compound (DMC) using dynamic mechanical thermal analysis (DMTA) and differential scanning calorimetry (DSC) techniques. Results obtained from the analysis have shown that the inhibition reaction is significant at molding temperatures, and a surprising correlation between surface finish and inhibition has been identified. STRESS RELAXATION IN DOUGH MOULDING COMPOUNDS
A. Cook, D. Dawson, and B. C. Duncan 1993 36 p
(PB94-124872; NPL-DMM(A)-110) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The stress relaxation of dough molding compounds (DMC's) has been investigated using the stress relaxation test developed at the National Physical Laboratory. Polyester and phenolic DMC's show acceptable load retention at room temperature. However, at 100 C, which is a more realistic operating temperature for the thermostat housing components, both materials show very rapid rates of stress relaxation. The degree of isothermal shrinkage experienced by these materials is relatively low, suggesting that viscoelastic stress relaxation is responsible for the poor load retention properties of these DMC's. None of the materials tested here has an acceptable service life and all perform worse than post-cured granular phenolic components. NTIS

This report documents an improved preparation of low density microcellular carbon as well as characterization of spatial homogeneity. The report also documents the process for preparing the microcellular carbon from polyacrylonitrile raw material. A microcellular polymer precursor (0.025 g/cc) is first prepared via a solution-based process and then pyrolyzed to produce the microcellular carbon in a monolithic form (0.05 g/cc). The process improvement developed in this study permits the pore structure of the microcellular polymer precursor and the microcellular carbon to be reproduced consistently in different laboratories. Pore structure is affected by the completeness of dissolution of the polymer raw material, which can be adjusted via dissolution temperature or particle size of the raw material. The second topic in this report involves determining the spatial fluctuation in mass density caused by periodic, millimeter-scale bands, known as 'tree rings,' visible on machined surfaces of the carbon monoliths. To measure the fluctuations, a high precision, spatially resolved x ray transmission technique was developed. The periodic bands caused less than +/- 2% variation of mass density in a microcellular carbon having average density 0.041 g/cc. DOE

AN INVESTIGATION OF CAVITATION IN A MECHANICALLY ALLOYED 15 VOLUME PERCENT SiCp/IN9021 ALUMINUM COMPOSITE
K. Higashi (Osaka Prefecture Univ., Sakai, Japan.), T. Okada (Osaka

Prefecture Univ., Sakai, Japan.), T. Mukai (Osaka Prefecture Univ., Sakai, Japan.), S. Tanimura (Osaka Prefecture Univ., Sakai, Japan.), T. G. Nieh, and J. Wadsworth Jul. 1993 8 p Presented at the International Union of Materials Research Societies on Advanced Materials, Tokyo, Japan, 31 Aug. - 4 Sep. 1993
(Contract W-7405-eng-48)
(DE94-003371; UCRL-JC-114736; CONF-9308122-16) Avail: CASI HC A02/MF A01

A mechanically alloyed 15 vol % SiC(sub p)/IN9021 aluminum composite exhibited a maximum elongation of 610 % at a very high strain of 5 s(exp -1) at 823 K. Nonetheless, the maximum elongation was obtained at a lower strain rate than that where the maximum m value (about 0.5) was obtained. This discrepancy between the optimum superplastic strain rate for the largest elongation and the strain rate for the maximum m value was believed to be associated with the cavitation behavior. Cavitation behavior of the SiC(sub p)/IN9021 aluminum composite was, therefore, carried out. It was found that cavities initiated at the ends of particulate reinforcements and parallel to the applied stress direction within initial small strains, and their subsequent growth and coalescence, invariably lead to premature failure. Experimental results indicate that cavity growth is plasticity controlled and can be described by a model proposed by Stowell. DOE

Anti-reflective coatings made with Teflon AF2400 had the highest damage thresholds recorded for physical vapor deposited coatings at the Lawrence Livermore National Laboratory damage facility. Physical vapor deposited layers of Teflon AF2400, a perfluorinated amorphous polymer, maintained the bulk optical properties of a high transmittance from 200 nm to 1600 nm, and a low refractive index. In addition, the refractive index can be intentionally reduced by control of two common deposition parameters, deposition rate, and substrate temperature. Scanning electron microscopy and nuclear magnetic resonance observations indicated that morphological changes caused the variations in the refractive index rather than compositional changes. The coatings adhered to fused silica and silicon wafers under normal laboratory handling conditions. DOE

(DE94-003660; DOE/ER-45370/T1) Avail: CASI HC A02/MF A01

This paper reports work on the study of ion containing polymers. X-ray absorption fine structure studies have been carried out on lightly sulfonated polystyrenes and polyurethane cationomers. In the polystyrenes, nickel, zinc, and cadmium-neutralized ionomers were studied. A simulation package, FEFF5, was available to model the polystyrenes, and the experimental data was input into the simulation to arrive at an atomic arrangement which fit the experimental data. The cationomers structure is still unresolved, and the question of water absorption is a problem for this system. NMR of Na-23 is also being used to study the local environment of the cation in sodium-neutralized lightly sulfonated polystyrene. Small angle neutron scattering experiments were also performed to explore the role of temperature in solution of sodium-neutralized carboxy-telechelic polystyrene ionomers in toluene. By adjusting the labelling levels and the angular range, the neutron scattering experiments probe either the aggregate structure or the single chain structure. DOE

ACCELERATED SCREENING METHODS FOR DETERMINING CHEMICAL AND THERMAL STABILITY OF REFRIGERANT-LUBRICANT MIXTURES. PART 2: EXPERIMENTAL COMPARISON AND VERIFICATION OF METHODS
R. Kauffman Oct. 1993 18 p
(Contract DE-FG02-91CE-23810)
(DE94-003664; DOE/CE-23810/20D-Pt-2) Avail: CASI HC A03/MF A01

Initial research focused on conductivity measurements to perform in heated situ degradation measurements of CFC-12/mineral oil and HCFC-22/mineral oil mixtures at 175 C in sealed glass tubes. Tungsten rods were sealed into round bottoms of the sealed tubes to provide electrical connections for in situ conductivity measurements. Steel, Cu, and W were used as catalysts as well as conductivity probes. Conductivity measurements have been made with both ac and dc voltage inputs. Preliminary results indicate that in situ conductivity measurements correlate with refrigerant/lubricant degradation as determined by other analytical techniques (color, gas chromatography). Some of the continuous conductivity measurement tests appear to accelerate as well as monitor the refrigerant/lubricant degradation. W posts with a valve steel catalyst appear optimum combination for conductivity measurements. Ferric fluoride catalysts and differential thermal analysis were also investigated. Initial tests indicate that the ferric fluoride catalyst has potential for testing lubricant stability at temperatures lower than 175 C. Differential thermal analysis have minimal potential for in situ measurements of long-term refrigerant/lubricant degradation processes. DOE

THE FORMATION OF CONDUCTING GOLD FILMS BY THERMAL DECOMPOSITION AND DIRECT PATTERNING USING ELECTRON BEAM LITHOGRAPHY OF THE GOLD CLUSTER Au55P(C6H5)312C16 Technical Report, Mar. 1992 - Dec. 1993
Ceceli A. Duchi, M. Kanskar, J. C. Wu, M. N. Wybourne, and Sui X. Cai 6 Dec. 1993 20 p
(Contract N00014-92-J-1412)
(AD-A273720; UO-JFWK-MNW-13) Avail: CASI HC A03/MF A01

The fabrication and electrical conductivities of conducting gold cluster films are presented. The films are deposited onto a Si3N4 substrate from a gold cluster solution by spin coating. After thermal decomposition and annealing at 180 C, a granular gold film with a resistivity of about 10(exp -6) ohms-m is formed. Resistivity measurements as a function of temperature show a low residual resistivity ratio. The low temperature resistivity indicates an electron mean-free-path close to the cluster diameter, and the temperature dependent resistivity is found to be in agreement with the Block-Gruneisen model. The spin coated gold cluster film also acts as a negative electron beam resist. Fine structures as small as 0.1 microns can be patterned directly by electron beam exposure. The electron beam exposed structures were found not to be conducting even after chemical extraction and firing. DTIC

COLLABORATIVE RESEARCH ON ION IMPLANTATION OF CERAMICS
C. J. McHargue 29 Jul. 1993 11 p
(Contract DE-AC05-84OR-21400)
(DE93-019177; ORNL/FTR-4702) Avail: CASI HC A03/MF A01 (US Sales Only)

Discussions were held with members of The Royal Institution of Great Britain on theoretical calculations in ceramic crystals relating to our ion-implantation results. Experiments were conducted by the staff of the National Institute for Engineering and Industrial Research (MTI) on sapphire crystals ion implanted at Oak Ridge National Laboratory (ORNL). Results of each experiment were analyzed in order to determine conditions for the next one. The results of recent experiments in France that are part of an ORNL University Claude Bernard collaboration in ion implantation of ceramics are discussed. Rain erosion and thermal shock tests on ORNL-supplied specimens of surface-modified sapphire and diamond have been completed at the Cavendish Laboratory. An invited paper, 'Ion Implantation-Induced Amorphization of Sapphire,' was presented at the International Conference on Mechanisms of Formation of Metastable Microstructures. Experiment details were discussed with Prof. T.F. Page for continuation. DOE

CRACKING OF TEXTURED ZINC COATING DURING FORMING PROCESS
Z. Mei and J. W. Morris, Jr. Sep. 1993 10 p Presented at the International Symposium on the Physical Metallurgy of Zinc Coated Steels: Processing, Structure and Properties, San Francisco, CA, 28 Feb. - 3 Mar. 1994
(Contract DE-AC03-76SF-00098)
(DE94-003414; LBL-34795; CONF-940235-1) Avail: CASI HC A02/MF A01

A model is presented to relate cracking of a zinc coating on steel during the forming process of its crystallographic texture. There are three deformation modes that can accommodate strains in a zinc coating caused by external loadings: basal slip, twinning, and cleavage cracking. Twinning of a zinc hexagonal crystal induces a contraction along its c-axis while cleavage relaxes tensile strain along its c-axis. Because of this, when basal slip in grains of a textured zinc coating is difficult under a given loading, either twinning or cleavage occurs depending on whether the basal plane is parallel or normal to the loading axis and whether the loading is tensile or compressive. The loadings during formability or surface friction tests cause twinning in the basal-textured coating and cleavage cracking in the prism-textured coating. The prism-textured coating contains in extraordinarily high hardness since none of the three deformation modes may be operative under compression. These results derived from the model are confirmed with recent studies on electrogalvanized steels. DOE

MICROPYROLYSIS OF POLYMER THIN FILMS FOR CERAMICS Ph.D. Thesis [MICRO-PYROLYSE DE COUCHES MINCES DE POLYMERS PRECURSEURS DE CERAMIQUES]
Sandrine Bec 1992 160 p In FRENCH Sponsored by Societe Rhone-Poulenc Chimie, France
(ECL-92-62; ETN-94-95280) Avail: CASI HC A08/MF A02

Polymer pyrolysis is one method to make ceramic coatings. With this technique, uncracked and adhering coatings thicker than 0.5 micrometers cannot be obtained. The aim is to understand spontaneous cracking phenomena during the transformation by pyrolysis of a thin polysilazane film into 'SiCN' ceramic. The analysis of the behavior of coatings pyrolyzed under various atmospheres is performed using a micropyrolysis apparatus. It allows in situ observation of the surface by optical microscopy during pyrolysis heat treatment. The changes during heating are demonstrated. It is shown that cracking during heating occurs at around 580 C under nitrogen or argon atmosphere. Chemical characterization shows that the coatings are SiCNO ceramic with an oxydized layer at their surface. Mechanical modeling and the construction of a one dimensional model allow the cracking and decohesion phenomena quantitatively to be described. Parameters which control these cracking phenomena are studied. Mechanical characterization of coatings at different stages of the pyrolysis treatment is done by nanoindentation. It is shown that the cracking occurs simultaneously with a large increase of the material's mechanical properties between 550 C and 650 C, coupled with a shrinkage at these temperatures. This shows that the cracking is due to the polymer/ceramic transition. ESA

THE FRACTURE BEHAVIOR OF A CVD CRYSTALLINE Si3N4/AMORPHOUS Si3N4 COMPOSITE
I. E. Reimanis, J. J. Petrovic, H. Suematsu, and T. E. Mitchell 1993 8 p Presented at the 1st Meeting of the Pacific Rim Ceramic Societies, Honolulu, HI, 7-10 Nov. 1993
(Contract W-7405-eng-36)
(DE94-002646; LA-UR-93-3614; CONF-931142-2) Avail: CASI HC A02/MF A01

The mechanical properties of a chemically vapor deposited alpha-Si3N4/amorphous Si3N4 composite were examined at 25 C and up to 1400 C using a microhardness tester. The composite consists of an amorphous matrix containing elongated alpha-Si3N4 particles (5-50 microns in diameter) which in some cases are radially microcracked. The conditions for spontaneous microcracking due to thermal residual stress are derived for a cylinder embedded in a matrix. Heat treatment of the composite at 1200 C results in a microstructure where the matrix consists of nanometer-sized particles separated by thin (50 A) layer of carbon. The indentation fracture toughness of the heat treated material improves remarkably due to extended microcracking through the carbon layer. DOE

BIOMEDICAL POLYURETHANE NETWORKS Ph.D. Thesis
Peter Bruin 1992 119 p
(ETN-94-95391) Avail: CASI HC A06/MF A02

The possibilities of using polyurethanes, especially cross linked ones, as biomaterials are investigated. The preparation, properties, and medical applications of some polyurethane networks are discussed. The design and synthesis of biodegradable lysine diisocyanate based elastomeric polyurethane networks are discussed. Its use as a material for the construction of a macroporous bottom layer (dermal analog) in two layer artificial skin is evaluated. The preparation and evaluation of a microporous polyetherurethane wound covering having a high water vapor permeability is considered. A two ply biodegradable microporous small caliber vascular prosthesis composed of polyurethane and poly(L-lactide) is described. The synthesis and properties of densely cross linked polyurethane networks, and their potential user in ophthalmology (intraocular lens, keratoprosthesis) are described. ESA

INERT STRENGTH OF PRISTINE SILICA GLASS FIBERS
W. L. Smith and T. A. Michalske Nov. 1993 5 p
(Contract DE-AC04-94AL-85000)
(DE94-004685; SAND-92-1107) Avail: CASI HC A01/MF A01

Silica glass fibers have been produced and tested under ultra high vacuum (UHV) conditions to investigate the inert strength of pristine fibers in absence of reactive agents. Analysis of the coefficient of variation in diameter, upsilon(sub d), versus the coefficient of variation of breaking strength, upsilon(sub sigma), does not adequately explain the variation of breaking stress. Distribution of fiber tensile strength data suggests that the inert strength of such fibers is not single valued and that the intrinsic strength is controlled by defects in the glass. Furthermore, comparison of room temperature UHV data with LN2 data indicates that these intrinsic strengths are not temperature dependent. DOE

CRYSTAL CHEMISTRY AND SELF-LUBRICATING PROPERTIES OF MONOCHALCOGENIDES GALLIUM SELENIDE AND TIN SELENIDE
A. Erdemir Feb. 1993 25 p Presented at the American Society of Mechanical Engineers/Society of Tribologists and Lubrication Engineers (ASME/STLE) Joint Tribology Cconference, New Orleans, LA, 24-27 Oct. 1993
(Contract W-31-109-eng-38)
(DE93-041177; ANL/MCT/CP-79124; CONF-9310170-1) Avail: CASI HC A03/MF A01

This paper describes the fundamentals of the crystal chemistry and self-lubricating mechanisms of two monochalcogenides; tin selenide and gallium selenide. Specifically, it enumerates their inter-atomic array and bond structure in crystalline states, and correlates this fundamental knowledge with their self-lubricating capacity. Friction tests assessing the self-lubricating performance of gallium and tin selenides were carried out on a pin-on-disk machine. Specifically, large crystalline pieces of gallium selenide and tin selenide were cut and cleaved into flat squares and subsequently rubbed against the sapphire balls. In another case, the fine powders (particle size approximately 50-100 microns) of gallium selenide and tin selenide were manually fed into the sliding interfaces of 440C pins and 440C disks. For the specific test conditions explored, it was found that the friction coefficients of the sapphire/gallium selenide and sapphire/tin selenide pairs were approximately 0.23 and approximately 0.35, respectively. The friction coefficients of 440C pin/440C disk test pairs with gallium selenide and tin selenide powders were on the orders of approximately 0.22 and approximately 0.38, respectively. For comparison, a number of parallel friction tests were performed with MoS2 powders and compacts, and the results of these tests were also reported. The friction data together with the crystal-chemical knowledge and the electron microscopic evidence supported the conclusion that the lubricity and self-lubricating mechanisms of these solids are closely related to their crystal chemistry and the nature of interlayer bonding. DESIGN OF A COMPUTER EXPERT SYSTEM FOR ADHESIVE SELECTION USING ARTIFICIAL INTELLIGENCE TECHNIQUES Technical Report
Karen L. Meyler and Joseph A. Brescia Nov. 1993 32 p
(AD-A274715; ARAED-TR-93021) Avail: CASI HC A03/MF A01

The Adhesives Section, Materials Technology Branch of the U.S. Army Armament Research, Development and Engineering Center was funded to design and build an expert system prototype capable of using artificial intelligence (AI) techniques to aid in the selection of a proper adhesive or sealant for Army material. The adhesives expert system prototype is designed to operate on an IBM-PC compatible 80486 computer having a minimum of four MB RAM and eight MB hard disc space. The system will operate using MS-DOS 5.0 Windows 3.1. Kappa PC version 2.1, a C-based application development and delivery environment for PC's by IntelliCorp, Inc. was identified as a suitable expert system shell program. The adhesives selector expert system (ASES) is currently being developed with this system using object-oriented programming techniques and rulebased reasoning. DTIC

NANOSCALE PLASTICITY IN SILICA GLASS
J. N. Glosli, D. B. Boercker, A. Tesar, and J. Belak Oct. 1993 6 p Presented at the American Society for Precision Engineering (ASPE) Conference, Seattle, WA, 7-12 Nov. 1993
(Contract W-7405-eng-48)
(DE94-004212; UCRL-JC-113769; CONF-9311102-5) Avail: CASI HC A02/MF A01

Mechanisms of nano-scale plasticity and damage initiation in silica glass are examined using molecular dynamics simulation. Computer experiments are carried out by indenting a sharp diamond-like tool, containing 4496 atoms, into a silica slab consisting of 12,288 atoms. Both elastic and plastic deformation of silica is observed during nanoindentation simulation; this transition occurs at an indentation of 1.25 nm, and the calculated hardness (15GPa for 1.5 nm indentation) agrees with experiment. DOE

THE DEPOSITION OF BORON NITRIDE AND CARBON FILMS ON SILICA GLASS FIBERS
W. L. Smith, T. A. Michalske, and R. R. Rye Nov. 1993 5 p
(Contract DE-AC04-94AL-85000)
(DE94-004684; SAND-92-1108) Avail: CASI HC A01/MF A01

A chemical vapor deposition technique is used to produce amorphous boron nitride and carbon thin films on high strength silica glass fibers. In this method, the fiber is drawn under ultra high vacuum conditions and low pressure process gases, in the presence of a hot tungsten filament, are used to grow films at low substrate temperatures. Films deposited with this technique do not degrade the intrinsic pristine strength of the silica fibers under dry conditions and, when stressed in chemically aggressive environments, act as effective barrier coatings. DOE

DEPOSITION OF a-SiC:H USING ORGANOSILANES IN AN ARGON/HYDROGEN PLASMA
Leon Maya 1993 7 p Presented at the Fall Meeting of the Materials Research Society, Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE94-004428; CONF-931108-18) Avail: CASI HC A02/MF A01

Selected organosilanes were examined as precursors for the deposition of amorphous hydrogenated silicon carbide in an argon/hydrogen plasma. Effect of process variables on the quality of the films was established by means of FTIR, Auger spectroscopy, XPS, XRD, chemical analysis, and weight losses upon pyrolysis. For a given power level there is a limiting feeding rate of the precursor under which operation of the system is dominated by thermodynamics and leads to high quality silicon carbide films that are nearly stoichiometric and low in hydrogen. Beyond that limit, carbosilane polymer formation and excessive hydrogen incorporation takes place. The hydrogen content of the plasma affects the deposition rate and the hydrogen content of the film. In the thermodynamically dominated regime the nature of the precursor has no effect on the quality of the film, it affects only the relative utilization efficiency. DOE

MECHANICAL PROPERTIES OF NANOPHASE MATERIALS
R. W. Siegel and G. E. Fougere Nov. 1993 29 p Presented at the North Atlantic Treaty Organization Advanced Study Meeting of Institute on Nanophase Materials, Corfu, Greece, 20 Jun. - 2 Jul. 1993
(Contracts W-31-109-eng-38; DE-FG02-86ER-45229)
(DE94-004625; ANL/MSD/CP-79851; CONF-9306223-3) Avail: CASI HC A03/MF A01

It has become possible in recent years to synthesize new materials under controlled conditions with constituent structures on a nanometer size scale (below 100 nm). These novel nanophase materials have grain-size dependent mechanical properties significantly different than those of their coarser-grained counterparts. For example, nanophase metals are much stronger and apparently less ductile than conventional metals, while nanophase ceramics are more ductile and more easily formed than conventional ceramics. The observed mechanical property changes are related to grain size limitations and/or the large percentage of atoms in grain boundary environments; they can also be affected by such features as flaw populations, strains and impurity levels that can result from differing synthesis and processing methods. An overview of what is presently known about the mechanical properties of nanophase materials, including both metals and ceramics, is presented. Some possible atomic mechanisms responsible for the observed behavior in these materials are considered in light of their unique structures. DOE

MODELLING AND PREDICTING PROPERTIES OF POLYMERS IN THE AMORPHOUS GLASSY STATE Ph.D. Thesis
Servatius Maria Vleeshouwer 1993 163 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-94-95345) Avail: CASI HC A08

The purpose of the work is the theoretical analysis of the glass transition and the glassy state of polymers, starting from equilibrium. The properties of the glassy state are related to the melt with the formation history as an important factor determining the nature of the glass. The description of the equation of state of polymer melts with the Holey-Huggins (HH) theory is reviewed. The free volume and free volume fluctuations defined in this theory are input parameter for the glass formation theory. A quasi equilibrium approach of the polymer glass with the HH theory is presented. Theories that describe and predict the glass transition and relaxation phenomena in glasses are given. The relation between mobility and free volume, temperature and pressure is examined and a new relation covering data sets is presented. The development of the glass formation theory from the RSC (Robertson, Simha and Curro) theory is presented. Six results, obtained with the glass simulation theory are discussed. The presence of molecular voids and their size distribution is approached from two opposite sides: theoretically, based on the HH theory, and experimentally, using positron lifetime spectroscopy. Samples of commercially produced, Poled lead Zirconate Titanate (PZT) piezoceramics were subject to longitudinal, compressive impact loading by a free falling striker providing a single, clean stress pulse. Values of the piezoelectric charge coefficient, d(sub 33) were derived and compared with those obtained via the conventional low frequency, low stress resonance method. The electrochemical coupling factor was also derived. The results obtained from the impact rig gave values for the d(sub 33) coefficient that are up to twice those gained from the resonance rig. Aging of the piezoelectric device under stress was studied by means of plotting d(sub 33) as a function of the number of impacts suffered. Samples of all the compositions displayed a drop in the values of d(sub 33) of between 18 and 49 when subject to 5000 impacts of approximately 40 MPa in magnitude. A sample of X-cut alpha quartz was subjected to the same tests as the PZT compositions. The quartz showed potential as a reference material for measurements of the piezoelectric response of impact loaded PZT ceramics. ESA

The results of a joint CEN/VAMAS (CEN/Versailles project on Advanced Materials and Standards) round robin on grain size measurement for advanced technical ceramics are analyzed. The round robin was established to verify the equivalence of line and circle methods for manual determination of mean linear intercept length proposed in a new CEN standard ENV 623-3, but also examined the possibilities of standardizing measurements of porosity and grain size distribution using overlaid grid intersection counting methods. Two alumina ceramics with very different microstructures and a computer drawn 'ideal' microstructure were used. The results show that scatter levels of 20% are obtained for measurement of the mean linear intercept length and the grain size distribution. They are primarily due to: quality of specimen preparation, selection of area for analysis, interpretation of features observed and, also random positioning of lines, circles, and grids on the micrograph. These levels of scatter are considered to be acceptable. The 30% scatter for the grid method porosity measurement is mainly due to the low level of very fine porosity in the nominally dense ceramic used and to the interpretation of a micrograph. The grid methods for grain size distribution measurement seem suitable for implementation in future standards. In all cases, the quality of micrograph preparation and interpretation needs further attention. ESA

STRESS-INDUCED PHASE TRANSFORMATION IN ZrO2 MATERIALS M.S. Thesis
Jianfeng Han 29 Jan. 1993 101 p
(ISBN-0-315-83373-4; CTN-94-61043) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

It is well known that the tetragonal to monoclinic transformation in zirconia ceramics is martensitic in nature and can be induced by applied stress. Transformation which results in enhanced toughness is particularly important. A study was conducted to develop a basic understanding of this driving stress through both experimentation and theoretical modeling. To characterize the stress which induces the transformation, an in-situ observation system was employed to examine the transformation event in a suitable localized stress field on a single edge-notched beam bar (SENB) whose stress distribution is modeled by finite element calculation. The real-time initiation of dendrite-like transformation bands was observed at the notch of SENB bars during in-situ loading experiments. The transformation was confirmed by Raman spectroscopy, and an important feature of the martensitic transformation was observed by laser microscopy. Based on a model developed from thermodynamics, the critical stress which induces transformation can be described by a combination of hydrostatic and deviatoric stress components. This stress was found to obey the Mohr-Coulomb criterion suggested by Chen and Morel, and its magnitude was observed to vary with grain size. The developed dendrite-like bands are discussed based on the concept of the autocatalytic effect. Author (CISTI)

ION BEAM MIXING OF MARKER LAYERS INTO AMORPHOUS ALUMINUM OXIDE
E. A. Cooper and M. Nastasi 1993 15 p Presented at the Nuclear Instruments and Methods in Physics Research on Radiation Effects in Insulators, Nagoya, Japan, Sep. 1993
(Contract W-7405-eng-36)
(DE94-000901; LA-UR-93-3278; CONF-9309259-1) Avail: CASI HC A03/MF A01

Thin layers of various marker species embedded in amorphous Al_2O_3 were ion beam mixed with 210 keV Ar in a temperature range of -166 to 790 C. All of the metal markers (Ag, Fe, and Zr) were found to mix only to a ballistic level. The oxide markers studied were Fe_2O_3, Cr_2O_3, Y_2O_3, and ZrO_2. Thermally assisted ion mixing was seen, in decreasing amounts, in Fe_2O_3, Y_2O_3, and Cr_2O_3. No thermally assisted ion beam mixing was observed for ZrO_2 or the metal markers. DOE

NEW RUBBER QUALIFICATION FOR THE IGNITER ADAPTER Final Report
Mark A. Humpherys 13 Jan. 1994 8 p
(Contract NAS8-38100)
(NASA-CR-193936; NAS 1.26:193936; TWR-65405) Avail: CASI HC A02/MF A01

Kirkhill Rubber Company (KRC) has informed Thiokol Corporation that two raw materials used in the asbestos and silica filled acrylonitrile butadience rubber (NBR) formulation per STW 2621 are no longer available from their vendors. Agerite White (Di-beta-naphthyl-paraphenylene diamine), manufactured by B. F. Goodrich, is an antioxidant used in NBR. This raw material makes up roughly 1-2 percent of the finished product. KRC proposed that this raw material be replaced by Agerite Stalite S (mixture of octylated diphenylamines) distributed by R. T. Vanderbilt Co. Protox-166 zinc oxide, manufactured by Zinc Corporation of America, is an activator currently used in NBR. This material also makes up about 1-2 percent of the finished material. Protox-166 is an American process grade zinc oxide. It is proposed by KRC to replace Protox-166 with Kadox-930C, a French process grade zinc oxide. American process grades have an ASTM minimum purity of 99.0 percent; the French process grades have a minimum purity of 99.5 percent. Previous testing per WTP-0270 has demonstrated that the mechanical and thermal properties of the rubber with the new ingredients are comparable to the 'old' rubber. The test results are reported in TWR-61790. One igniter adapter, Part no. 7U77562-02 serial no. 2 was insulated per ETP-1206 using the new rubber formulation and a modified lay up and cure method to demonstrate that there is no impact on this process. The results of this demonstration are reported. Author (revised)

X RAY ABSORPTION STUDIES OF Ti/POLYMER AND Cr/POLYMER INTERFACES
R. L. Opila (Bell Telephone Labs., Inc., Murray Hill, NJ.), K. Konstadinidis (Bell Telephone Labs., Inc., Murray Hill, NJ.), A. O Ibidunni (Bell Telephone Labs., Inc., North Andover, MA.), A. J. Davenport, and H. S. Isaacs 1993 6 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contract DE-AC02-76CH-00016)
(DE94-003008; BNL-48489; CONF-930405-49) Avail: CASI HC A02/MF A01

The interface formed between metals (Ti and Cr) and polymers (epoxy and triazine) have been studied, non-destructively, using x-ray absorption spectroscopy. The metals were sputtered onto the polymer surfaces. Titanium reacts extensively, up to Ti thickness of 100 A while Cr remains primarily metallic. In situ heating at 200 C increases the extent of reaction for both metals. Heating has a greater effect on metal/epoxy interfaces than metal/triazine. Titanium and Cr were ion implanted into the polymer in order to determine the interactions of isolated metal atoms with the polymer. Titanium and Cr appear to form oxides as the final reaction product, and the Ti is tetrahedrally coordinated. DOE

Thin film organic nonlinear optical (NLO) materials are being investigated for laser hardening applications due to their enhanced processability. Plasma-polymerized thiophene films formed by the flowing afterglow synthesis of polyaromatic heterocycles allow one to modulate the refractive index profile in real-time, thus allowing an organic analog of a rugate to be realized. Since the relationships between the molecular structure, NLO response, and processing conditions are poorly understood, the feasibility of using x ray absorption fine structure (XAFS) spectroscopy was examined. This method allows the local environment of x ray absorbing atoms in polythiophene and plasma-polymerized 2,5 dichlorothiophene and 2,5 dibromothiophene thin films at the sulfur K-edge and, as appropriate, the chlorine and bromine K-edges to be probed. Argon absorption was found to limit the data range of the S and Cl edge data. The Br K-edge data indicated that the local Br environment was maintained in the plasma-polymerized films of 2,5 dibromothiophene within experimental error. As a result, XAFS spectroscopy has been shown to be a useful technique for investigating the molecular structure of an important category of nonlinear optical materials. DTIC

Thin specimens (approx. 10 mils) can be tested using an ultrasonic technique to determine their moduli and Poisson's ratio. For this report, the thin specimen's ultrasonic response is FFT analyzed in an attempt to extend the technique for cure monitoring of polymeric systems. Two such systems are examined and the ultrasonic results compared with differential scanning calorimetry and dynamic mechanical measurements. Two parameters were measured as a function of time: the ultrasonic peak frequency and amplitude. The results suggest that it may be possible to monitor the cure through observation of these two parameters. DTIC

MECHANICAL PROPERTIES OF POLYANILINE PREPARED BY POLYMERIZATION IN AN ORGANIZED MONOLAYER Technical Report No. 2
Raj Bodalia and Randolph Duran 9 Dec. 1993 5 p
(Contract N00014-91-J-1655)
(AD-A274350) Avail: CASI HC A01/MF A01

Poly (2-penta decyl aniline) was prepared at the air-aqueous acid interface using the Langmuir film balance technique. Compressional modulus of polymers prepared at different conditions were measured from surface - pressure - area isotherms. Mechanical properties of polymers prepared at different applied surface pressures were found to remain unchanged while those of polymers prepared at different temperatures changed significantly. A lower compressional modulus obtained at higher temperature can be related to its lower molecular weight. These results fit very well with the theoretical model. This study indicates that polymers with better mechanical properties can be obtained by carrying out the reaction at a lower temperature. DTIC

EQUIVALENT PERFORMANCE IN DIFFERENT HELICAL RESONATOR PLASMA POLYMERIZATION COATER PLATFORMS
R. M. Brusasco Nov. 1993 19 p Presented at the 40th National Symposium of the American Vacuum Society (AVS), Orlando, FL, 15-19 Nov. 1993
(Contract W-7405-eng-48)
(DE94-001517; UCRL-JC-113724; CONF-9311104-4) Avail: CASI HC A03/MF A01

Plasma polymerization is used in fabricating target mandrels for implosion experiments on the NOVA laser. As part of effort to translate the theoretical aspects of plasma polymerization fundamentals into practical improvements in a production oriented environment, a study was done to determine the cause of differences in polymer deposition characteristics between two similar plasma polymerization devices. Full characterization of the coating system parameters revealed differences in the flow rate, RF power dissipation and system pressure which were subsequently changed to make the coaters equivalent in this sense; this was found insufficient to ensure equivalent performance. An experiment designed to test effect of changing operating conditions of helical resonator plasma applicator indicated that the cause of performance discrepancy did not lie with the plasma generation equipment. Substrate positioning was found to be a critical factor in determining the deposition rate of plasma polymer but played no significant role in the development of rough surfaces. Surface texture was dependent upon gas flow rates and RF power dissipation. DOE

The cleaning and etching of the vicinal alpha (6H)-SiC(0001) surface has been emphasized in this reporting period because of its recently demonstrated importance in the MBE of SiC and AlN films on SiC wafers and layers. Etching with a solution of 1:1:10HF:H2: ethanol and a hydrogen plasma sharply reduced both the oxide and the C surface concentrations as determined by AES and XPS spectra. Controlled growth of both Beta-SiC and alpha (6H)-SiC films have been achieved on SiC wafers and films. Flow ratios of C2H4 and Si2H6 of 1:1 result in 6H-SiC while C-rich ratios give 3C-SiC. Surface reconstruction as a function of surface treatment have also been related to the deposited SiC polytype. The initial stages of AlN film growth has also been investigated in terms of defects via TEM. Two types of defects were found in the AlN film: one caused by lattice mismatch; the other by the presence of steps in the SiC surface. The interfacial chemistry and microstructure, electrical properties and the Schottky barrier heights of thin films on Alpha (6H)-SiC(0001) surfaces were investigated after annealing to 700 deg C and a maximum time of 60 min. The reaction zone contained Ti5Si3 and TiC. The electrical properties changed little as a function of heat treatment. DTIC

LB-DEPOSITED, SIDE-CHAIN SUBSTITUTED POLYANILINE, POLYPYRROLE AND THE CORRESPONDING MONOMERS, STUDIED BY STM Technical Report No. 22
P. Quint, T. Bailey, W. Sigmund, and R. S. Duran 9 Dec. 1993 5 p
(Contract N00014-91-J-1655)
(AD-A274405) Avail: CASI HC A01/MF A01

STM investigations were carried out on monolayers of two conducting polymers and the corresponding monomers. The substances in question--2-pentadecyl aniline, poly-2-pentadecyl aniline, 3-hexadecyl pyrrole, and poly-3-hexadecyl pyrrole--were transferred from the liquid/air interface on a MoS2 substrate by the Langmuir-Blodgett technique. The polymers were polymerized at the liquid/air interface with ammonium persulfate in the sub phase as the oxidizing agent. All compounds showed high orientational and positional order on the substrate surface. Two different structures were observable, rows and rod like structures. The distance between the rods was found, for all compounds, to be equal to 4.3 A. The row distances were found to be different for every substance. We think that the rods are the alkyl side chains, and the rows represent the polymer chain or molecular monomer aggregates. DTIC

ENGINEERING LIMITATIONS OF CERAMIC COMPOSITES FOR HIGH PERFORMANCE AND HIGH TEMPERATURE APPLICATIONS
E. L. Courtright Aug. 1993 12 p Presented at the Conference on Processing, Fabricating and Application of Advanced Composites: Putting MMCs, CMCs and PMCs To Work, Long Beach, CA, 9-11 Aug. 1993
(Contract DE-AC06-76RL-01830)
(DE94-001676; PNL-SA-22816; CONF-930858-1) Avail: CASI HC A03/MF A01

Some of the engineering limitations of ceramic matrix composites in high-temperature applications are reviewed in terms of fundamental properties. The issues associated with toughness control in the regimes where fiber pullout is not extensive are discussed. Toughening will decrease with increasing temperature because fiber strength decreases and interfacial sliding resistance increases. The temperatures regime where reinforcement fibers become creep limited, as opposed to strength limited, will influence design considerations. Matrix cracking becomes an important high temperature design limiting parameter, particularly where oxygen can rapidly gain access to bridging fibers. Even the direct permeation of oxygen through uncracked matrices may be sufficient to internally degrade fibers and limit performance in some systems. DOE

FERROELECTRICITY IN A LANGMUIR-BLODGETT MULTILAYER FILM OF A LIQUID CRYSTALLINE SIDE-CHAIN POLYMER
S. Pfeiffer, R. Shashidar, T. L. Fare, J. Naciri, and J. Adams 12 Sep. 1993 13 p
(Contract N00014-91-J-1655)
(AD-A274477; TR-17) Avail: CASI HC A03/MF A01

The first observation of ferroelectric behavior in a Langmuir-Blodgett (LB) film of a liquid crystalline polymer is reported. It is established that a 30-layer film exhibits spontaneous polarization and electro-optic switching. The magnitude as well as temperature dependence of the polarization of the LB film is found to be similar to that of the bulk material. The polarization current in the LB film follows the applied triangular wave field to higher frequencies as compared to the same material in a surface stabilized sandwich cell. DTIC

LIQUID CRYSTALLINE SIDE-CHAIN POLYSILOXANES WITH 4-AMINO-4'-STILBENE-CARBOXYLIC ESTER MESOGENS
Marietta O. Bautista, Warren T. Ford, R. S. Duran, and Matthias Naumann 9 Dec. 1993 5 p
(Contract N00014-91-J-1655)
(AD-A274510; TR-19) Avail: CASI HC A01/MF A01

The liquid crystalline phases of polysiloxanes have been characterized by DSC, optical microscopy, and powder x ray diffraction. The polysiloxanes form monolayers at the air/water interface with molecular areas of 30 - 35 A(exp 2), and the films do not collapse at pressures of about 40 mN/m. The monolayers of CPS-1 and -2 showed good stability on water compared to those of HPS-1 and -2 as measured by isobaric surface area changes as a function of time. Moreover, there was little hysteresis between isotherms obtained by compression and subsequent decompression below 40 mN/m for CPS-1 and -2. DTIC

KINETICS OF 2-PENTADECYLANILINE POLYMERIZATIONS IN MONOLAYERS: RELATIONSHIPS BETWEEN EXPERIMENTAL DATA AND A NEW THEORETICAL MODEL
Raj Bodalia, Randolph S. Duran, Jose Manzanares (Valencia Univ., Spain.), and Howard Reiss (California Univ., Los Angeles.) 12 Sep. 1993 38 p
(Contract N00014-91-J-1655)
(AD-A274419; TR-20) Avail: CASI HC A03/MF A01

A simple theoretical model that provides a detailed understanding of aniline polymerization kinetics in a monolayer is presented. Even though the model is primitive, it agrees very well with our experimentally measured data. The rate constant and activation energy obtained in our previous study from the modified Gee and Rideal-equation were found as geometric and arithmetic means, respectively, of values which correspond to the initiation and propagation steps. This model allows us to predict an average degree of polymerization and thus an average molecular weight and the fraction of reacted monomer at any stage during the polymerization reaction. Also, some predictions regarding the temperature dependence of molecular weight can be made from this model. DTIC

ULTRASTRUCTURE PROCESSING OF MACROMOLECULAR MATERIALS Final Technical Report
Frank E. Karasz 11 Feb. 1993 23 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-90-C-0019)
(AD-A274460) Avail: CASI HC A03

The research has concurrently involved several areas of investigation in the physical chemistry of macromolecules. A major theme was the study of the properties of polymer blends. Experimentally the effects of microstructure on miscibility in a number of model systems was investigated by thermal, mechanical, and varied spectroscopic techniques, and a wide understanding of the fundamental basis of the metastable miscibility found in an unexpectedly large number of high temperature systems, i.e. these typically involving polyimides or related materials with high Tg's was gained. In complementary investigations, computer simulation studies of the equilibrium behavior of various blends and under several relevant constraints were performed. The work also investigated dynamic aspects, particularly phase separation at differing effective quench depths. Another line of investigation concerned itself with electro-optically active conjugated polymers, principally poly(p-phenylene vinylene) and its derivatives, modifications and blends. Certain solution properties of polymer systems were also studied. Measurements were taken to investigate translational diffusion of solvated polymers in porous media and other properties of polar and non-polar macromolecules. DTIC

LANGMUIR-BLODGETT AND STM INVESTIGATIONS OF CONDUCTING POLYMER THIN FILMS

R. S. Duran, W. Sigmund, T. Bailey, and M. Hara 16 Dec. 1993 5 p
(Contract N00014-91-J-1655)
(AD-A274512; TR-23) Avail: CASI HC A01/MF A01

The monomer 3-hexadecyl pyrrole was spread and polymerized at air/aqueous interfaces using a Langmuir trough. During polymerization under isobaric conditions, a monotonic decrease in surface area was observed; however, upon expansion and recompression of the monolayer, the surface area for the polymer was found to be larger than that of the monomer. Monomer and polymer monolayers were also transferred to solid supports and studied by scanning tunneling microscopy. DTIC

PHOSPHAZENE-CONTAINING AMINE AS CURING AGENT FOR PHTHALONITRILE-BASE POLYMER Patent

Teddy M. Keller, inventor (to Navy) 4 May 1993 6 p Filed 15 Mar. 91
(AD-D016029; US-Patent-5,208,318; US-Patent-Appl-SN-670; US-Patent-Class-528-168) Avail: US Patent and Trademark Office

Phosphazene-containing amines having at least one amine or substituted amine moiety reactive with nitrite groups of the phthalonitrile monomers or oligomeric resins are useful curing agents for phthalonitriles. Typically, the phosphazene-containing amines useful as curing agents in the present invention have the formula: wherein each of X(1-6) is a hydrogen, an unsubstituted amine group, or an amine group substituted with C1-C12 alkyl groups or aromatic groups, at least one of X(1-6) includes an amine group, and each of R'(1-6) is an alkyl, aromatic, or alkyl-substituted aromatic moiety, or a linear polymer of the phosphazene-based amine monomer. The curing agents enhance the speed of cure and also add flame retardancy to the cured polymers. DTIC

N94-27148 Department of the Navy, Washington, DC.

ACCORDION-LIKE POLYMERS FOR NONLINEAR APPLICATIONS Patent

John D. Stenger-Smith, inventor (to Navy), Ronald Henry, inventor (to Navy), James Hoover, inventor (to Navy), Geoffrey Lindsay, inventor (to Navy), and John Fischer, inventor (to Navy) 21 Sep. 1993 18 p Filed 20 Mar. 92
(AD-D016031; US-Patent-5,247,055; US-Patent-Appl-SN-856437; US-Patent-Class-528-310) Avail: US Patent and Trademark Office

The present invention discloses new polymers which can assume an accordion-like conformation of the backbone. These polymers are prepared by the copolymerization of two difunctional, chemically precoupled precursors to chromophoric units. The resulting polymers have a head-to-head, tail-to-tail topology (a syndioregic arrangement of rigid units along the polymer backbone), and the molecular units are designed to fold into an accordion conformation. This useful microstructure (a three-dimensional conformation) forms spontaneously (self-assembles); or, it can be brought about by field-assisted processing. Films and fibers of these polymers have useful second-order nonlinear optical properties, and may be used for the modulation and switching of optical communications signals. DTIC

CHEMICAL POLYMERIZATION AND LANGMUIR-BLODGETT TECHNIQUES. 2: THE POLYMERIZATION OF MONOLAYERS OF 3-SUBSTITUTED PYRROLES

W. M. Sigmund, C. Marestin, S. Keil, H. Zhou, Randolph S. Duran, M. Z. Elsabee (Cairo Univ., Egypt.), J. Ruehe (Max-Planck-Inst. fuer Polymerforschung, Mainz, Germany.), and G. Wegner (Max-Planck-Inst. fuer Polymerforschung, Mainz, Germany.) 12 Sep. 1993 34 p
(Contract N00014-91-J-1655)
(AD-A274478; TR-24) Avail: CASI HC A03/MF A01

Derivatives of 3-substituted pyrroles were spread at the air-water interface. Stable films could be obtained for pyrroles with side chains containing more than 10 carbons. 3-Hexdecanoyl pyrrole could not be polymerized as a monolayer whereas the alkyl derivatives could be polymerized successfully without having additional monomer in the subphase. It was possible to yield a true two-dimensional polymer monolayer film, without chain overlapping. The monolayers could be transferred onto hydrophobized substrates with transfer ratios being about unity. The polymers formed were soluble in chloroform and THF. Molecular weight averages obtained by GPC ranged from 3,500 to 6,000 when polymerized on ammonium peroxodisulfate and 5,000 to 15,000 when polymerized on ferric chloride subphase solutions. H-1 NMR indicates that the polymerization is highly regular, leading to a constitutionally ordered 2,5 poly(3-alkyl pyrrole). DTIC

N94-27203 Department of the Navy, Washington, DC.

THERMOPLASTIC ELASTOMERS HAVING ALTERNATE CRYSTALLINE STRUCTURE FOR US AS HIGH ENERGY BINDERS Patent

Gerald E. Manser, inventor (to Navy) and Richard S. Miller, inventor (to Navy) 11 May 1993 8 p Filed 6 Jan. 92
(AD-D016035; US-Patent-5,210,153; US-Patent-Appl-SN-815878; US-Patent-Class-525-410) Avail: US Patent and Trademark Office

Block polymers which are thermoplastic elastomers are provided for use as binders in high-energy compositions such as propellants, explosives, gasifiers or the like. The block polymers have an ABA structure wherein the A blocks are crystalline at temperatures below 60 C and the B blocks are amorphous at temperatures above -20 C. Both the A and B blocks are polyethers formed from monomers of oxetanes and/or tetrahydrofuran. The block polymers melt in the range of 60 C to 120 C and have low viscosities above their melting points due to mutual miscibility of the A and B blocks. DTIC

INTELLIGENT MATERIAL SYSTEMS AND STRUCTURES. PART 6: MEASUREMENTS OF ADHESION BETWEEN OPTICAL FIBRES AND COMPOSITE MATERIALS [INTELLIGENTA MATERIALSYSTEM OCH STRUKTURER. DEL 6: METODER FOER ATT BESTAEMMA VIDHAEFTNING MELLAN OPTISKA FIBRER OCH MATRISMATERIAL]
J. Schoeld Jun. 1993 36 p In SWAHILI; Text in SWEDISH; summary in ENGLISH See also PB93-195923 and PB93-204600
(PB94-123577; FOA-C-20934-8.4-Pt-6) Avail: Issuing Activity (National Technical Information Service (NTIS))

The concept 'Intelligent Material Systems and Structures' (IMSS) includes structurally embedded sensors and actuators. The adhesion between sensors and matrix is essential for the performance of the system. The adhesion between two types of optical fibers and the matrix (two types of epoxy resin) was investigated, since optical fibers may potentially be used as sensors in polymer fiber composites. There is a lack of knowledge concerning measurements of adhesion between optical fibers and composite materials. Several methods were however developed for measurements of adhesion between reinforcing fibers and matrix materials. A literature survey of these techniques is included. NTIS

ULTRASONIC MEASUREMENT TECHNIQUE TO DETERMINE THE STATE OF CURE IN THERMOSETTING MATERIALS
P. A. J. Gibbs, M. Rides, and P. Williamson 1993 21 p
(PB94-124328; NPL-DMM(A)-114) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The possibility of using ultrasonics as a non-destructive test method for determining the state of cure in thermosetting materials is investigated. Four variations of an unsaturated polyester molding material were used to evaluate ultrasonics for cure monitoring. The test materials were each cured at a series of test temperatures up to 100 C. During cure the changes in velocity and attenuation of a transmitted ultrasonic pulse were measured at regular intervals. The ultrasonic velocity and attenuation measurements were then related to the test material's state of cure. NTIS

MATERIALS CHARACTERIZATION ON EFFORTS FOR ABLATIVE MATERIALS Final Report
Thomas P. Tytula, Kristin C. Schad, and Myles H. Swann Sep. 1992 53 p
(Contract NAS8-38609)
(NASA-CR-193929; NAS 1.26:193929; UAH-QERL-92-1) Avail: CASI HC A04/MF A01

Experimental efforts to develop a new procedure to measure char depth in carbon phenolic nozzle material are described. Using a Shor Type D Durometer, hardness profiles were mapped across post fired sample blocks and specimens from a fired rocket nozzle. Linear regression was used to estimate the char depth. Results are compared to those obtained from computed tomography in a comparative experiment. There was no significant difference in the depth estimates obtained by the two methods. Author

TECHNICAL REPORT OF ISSP. SER. A, NO. 2673: TWO SUCCESSIVE SPIN GLASS TRANSITIONS IN NON-DILUTED HEISENBERG-LIKE SPIN GLASS Ni(0.42)Mn(0.58) TiO3
Hazuki Kawano, Hideki Yoshizawa, Atsuko Ito, and Kiyoichiro Motoya Apr. 1993 14 p
(ISSN 0082-4798)
(JTN-94-80559) Avail: CASI HC A03/MF A01

Two successive Spin Glass (SG) transitions were observed in a non-diluted Heisenberg-like SG system with a weak planar single-ion anisotropy, Ni(0.42)Mn(0.58)TiO3. The moment lying in the easy plane freezes at T(sub SG)(sup parallel) = 9.5 +/- 1.0 K, while the remaining component perpendicular to the easy plane freezes at a lower temperature T(sub SG)(sup perpendicular) = 6.0 +/- 0.5 K, being consistent with theory on the Heisenberg-like SG system with a weak single-ion anisotropy. The diffuse scattering profile is well described by a Lorentzian in an intermediate phase T(sub SG)(sup parallel) greater than or equal to T greater than T(sub SG)(sup perpendicular) as well as in a paramagnetic phase T greater than T(sub SG)(sup parallel), whereas it strongly deviates from the Lorentzian below T(sub SG)(sup perpendicular). DUAL CURE LOW-VOC COATING PROCESS Semiannual Report, 1 Apr. - 30 Sep. 1992
K. E. Kinzer Oct. 1993 38 p
(Contract DE-AC04-88ID-12692)
(DE94-000365; DOE/ID-12692/4) Avail: CASI HC A03/MF A01

The objective of Phase 3 of 3M's contract with the U.S. Department of Energy is to complete proof-of-principle testing in full-scale systems of the dual cure photocatalyst technology developed in earlier Phases of the program. The Phase 3 commercial applications to be demonstrated are aerospace topcoats, aerospace primers, and solventless manufacture of tape backings. This report details activities of Phase 3 during this reporting period. In the second six months of Phase 3, work has continued in all three applications. Significant progress has been made in improving the performance of the urethane/acrylate formulation being used for the aerospace topcoat application. Key improvements have been made in obtaining increased reverse impact, initial gloss and gloss retention during accelerated weathering. Technical challenges have continued with the aerospace primer formulation. Efforts in this six months have continued to focus on establishing a good baseline epoxy/acrylate formulation with reliable cure conditions. Work on the third demonstration application, development of solventless backing saturants for electrical tape backings, has essentially been completed. Optimal dual cure resin formulations have been identified and utilized in preparing complete tape constructions. These tapes have been evaluated and characterized in terms of benchmark UL and internal 3M specifications for electrical tape performance. DOE

DISCRETE VACUUM ULTRA VIOLET REFLECTIVE INTERFERENCE FILTER Patent Application
William R. Hunter, inventor (to Navy) and James P. Long, inventor (to Navy) 27 Jun. 1993 22 p
(AD-D016059; US-Patent-Appl-SN-099489; Navy-Case-74607) Avail: CASI HC A03/MF A01

A thin film reflecting interference filter (RIF) is designed to suppress unwanted harmonics thereby improving the monochromaticity of the radiation. An interference layer of material which has a well-defined plasma oscillation is deposited on a substrate and a mismatch layer is formed thereon. This interference layer exploits the interference between wavefronts reflected from the layer-substrate and the vacuum-layer interfaces to suppress higher order harmonics, while allowing good reflectance at the fundamental wavelength. This is achieved by positioning the RIF in the radiation at an angle of incidence which is greater than the critical angle of the desired fundamental wavelength, but less than critical angles of the harmonics to be suppressed. The mismatch layer increases the reflectance of the unwanted harmonics at the vacuum-layer interface, thus allowing more complete destructive interference of the unwanted harmonics. The RIF can be tuned by altering the thickness of the layer, the composition of the layer, and/or the angle of incidence of the radiation. Author (DTIC)

COMPATIBILITY OF REFRIGERANTS AND LUBRICANTS WITH ENGINEERING PLASTICS
R. C. Cavestri Dec. 1993 167 p

(Contract DE-FG02-91CE-23810)
(DE94-004959; DOE/CE-23810/15) Avail: CASI HC A08/MF A02

Twenty-three plastics have been subjected to immersion studies using seven different lubricants at 60 C and 100 C, and 10 different refrigerants at ambient and 60 C. In the first part of the study, 22 hermetic stress crack-creep rupture test chambers were used to determine dynamic effects of a constant dead weight load on plastic test bars immersed at 20 C in a 40% refrigerant 32 ISOVG branched acid polyolester lubricant. The creep modulus data of the 10 refrigerants, using a dead weight load of 25% of ultimate tensile, are compared to values for air and HCFC-22. In the second part, the plastic test bars were aged for 14 days at constant refrigerant pressure 300 psia with 17 refrigerant lubricant combinations at 150 C. Additional evaluations were conducted to elucidate the effects of temperature, refrigerant, and lubricant on the plastics. At 150 C, high acid formation (high TAN) was further examined with dehydrated plastics. These evaluations indicate that dehydrating the plastics reduced, but did not eliminate, high TAN values and that heat alone caused the lost physicals. Alternative HFC refrigerants had little impact on plastics; some polyolester lubricants caused identifiable changes. DOE

SYNTHESIS, RHEOLOGY, AND FORMING OF Y-Ba-Cu-O CERAMICS Ph.D. Thesis
T. M. Green Jul. 1993 145 p
(Contract W-7405-eng-82)
(DE94-005558; IS-T-1642) Avail: CASI HC A07/MF A02

A chemical synthesis route is discussed which results in a low temperature precursor to YBaCuO ceramics; it is based on use of molten Ba(OH)2 8H2O flux. Two different chemical systems have been examined; the first one, based on nitrate salts, has been demonstrated to be a viable precursor material for tape casting and extrusion; the second, made from acetate salts, has been used for powder synthesis and extrusion. Rheology of pastes shows that their flow may be fit to either Bingham plastic or Hershel-Bulkley models. Yield stress is controlled in both pastes by volume fraction solids. Viscosity also follows solids loading in the paste. Shear thinning is controlled by colloidal nature of precursor. The paste has colloidal microstructure. Comparison of concentric cylinder rheometry and piston extrusion rheometry shows order of magnitude differences in yield stress, resulting from the test method and paste dilation. DOE

Feigelson (Stanford Univ., CA.), and R. K. Route (Stanford Univ., CA.) Dec. 1993 12 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract W-31-109-eng-38)
(DE94-005120; ANL/MSD/CP-81580; CONF-931108-36) Avail: CASI HC A03/MF A01

The solid source MOCVD technique, employing a single powder vaporization source composed of mixed beta-diketonate metalorganic compounds, has been used to grow thin films of a variety of electro-optic materials including lithium niobate, strontium barium niobate, and potassium niobate. Preliminary results for potassium niobate films indicate that a volatile potassium organometallic source can be useful for growing potassium niobate by MOCVD. High single phase (001) oriented strontium barium niobate films have been deposited which exhibit waveguiding behavior. The most extensive work has been done on lithium niobate deposited epitaxially on a variety of substrates. Oriented z-axis (001) films have been grown on c-axis sapphire with and without a (111) oriented platinum base electrode and on a bulk grown lithium niobate substrate. Films grown directly on c-axis sapphire at 700 C exhibit x-ray rocking curve linewidths as low as .044 degrees, nearly perfect in-plane orientation as determined by x-ray phi scans, and a peak-to-peak surface roughness of less than 40 A. Optical waveguiding has been demonstrated by single prism coupling technique on similar films 1175 - 2000 A thick grown at 500 C, with optical losses of approximately 2 db/cm at 632.8 nm measured over 3.5 cm long films. Polarization vs. electric field measurements on 1100 A thick films grown on platinum show a hysteresis loop indicating ferroelectric behavior. DOE

Cr-based corrosion resistant undercoatings will have to be replaced because of environmental and health concerns. A coating system of a conducting polyaniline primer layer topcoated with epoxy or polyurethane, is being evaluated for corrosion resistance on mild steel in 0.1 M HCl or in a marine setting. Results of both laboratory and Beach Site testing indicate that this coating is very effective; even when the coatings are scratched to expose bare metal, the coated samples show very little signs of corrosion in the exposed area. ELECTROCHEMICAL PROPERTIES OF PASSIVE FILMS ON 440C STAINLESS STEEL Ph.D. Thesis
Timothy Lawrence Walzak Oct. 1990 384 p
(ISBN-0-315-64248-3; CTN-94-60994) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Type 440C stainless steel is a high-C, high-Cr martensitic steel used in applications requiring high hardness and wear resistance in combination with moderate corrosion resistance. Typical applications include precision aerospace bearings and critical components in computer disk drives. The properties of passive films formed on 440C steel were investigated using advanced electrochemical techniques with a view to establishing a method to measure film stability directly in the passivation baths. Electrochemical measurements were sensitive to the passive film properties and were able to quantify the effect of cooling rate on passive film stability. The techniques used included linear polarization, AC impedance, small amplitude cyclic voltammetry, and coulostatic transient measurements. These provided results that exhibited excellent agreement with the AC impedance technique providing the most information about the interfacial reactions. It was found that the full electrochemical characterization of the passive film stability required evaluation of both the polarization resistance and the interfacial capacitance, thus precluding use of DC measurements. The coulostatic technique demonstrates the most promise as a monitoring tool as it provides a rapid, simple measurement of both the polarization resistance and capacitance. Author (CISTI)

OUTGAS AND VACUUM SEAL CHARACTERISTICS OF IRRADIATED POLYIMIDE O-RING
Takuya Terakado (Japan Atomic Energy Research Inst., Naka.), Kiyoshi Shibanuma (Japan Atomic Energy Research Inst., Naka.), Yoshinao Ohkawa (Japan Atomic Energy Research Inst., Naka.), and Tadao Seguchi (Japan Atomic Energy Research Inst., Takasaki.) Mar. 1993 49 p
(DE94-701200; JAERI-M-93-067) Avail: CASI HC A03/MF A01

In application of polymeric materials to the fusion experimental reactor, outgas and vacuum seal characteristics of irradiated polyimide were studied. Crystalline polyimide is used as a test specimen, which is cut into the equivalent of O-ring V40 for JIS vacuum flange 25A. Irradiation conditions of the test specimen are three, i.e., absorbed dose 0, 5 and 10 MGy corresponding to 0, 50 and 100 hours of irradiation, respectively, under the induced dose rate of 10(exp 5) Sv/h in the vacuum vessel after shutdown of the experimental reactor, and temperature conditions of the test specimen are room temperature, 180 C, baking temperature of the vacuum vessel, and 350 C, baking temperature of plasma facing components, such as the divertor and the first wall. In outgas characteristic, outgassing rate and outgas mass spectra were measured, and in vacuum seal characteristic, the relation between helium leak rate and compression ratio of the test specimen was evaluated. By comparing the test results, outgassing and vacuum seal characteristics of irradiated polyimide O-ring were clarified. DOE

FRAGMENTATION OF Ge(1-x) Sn(x) Se2 GLASSES
G. Saffarini Aug. 1993 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-603009; IC-93/246) Avail: CASI HC A03 (US Sales Only)

Density, differential scanning calorimetry (DSC), X-ray diffraction (XRD), and X-ray photoelectron spectroscopy (XPS) measurements of Ge(1-x)Sn(x)Se2 within 0.0 less than or equal to x less than or equal to 0.6 have been obtained. Upon increasing the Sn content, the density measurements show a non-monotonic decrease, while the differential scanning calorimetry measurements show a monotonic decrease of the glass transition temperature. The X-ray diffraction measurements on these glasses give interference functions which have first sharp diffraction peaks (FSDP) indicating the presence of intermediate range order (IRO). The X-ray photoelectron spectroscopy measurements were used to determine the plasmon energies from the L(sub 3)M(sub 4,5)M(sub 4,5) selenium Auger peaks which may be looked upon as being determined by the local electron density about the selenium atoms. It is found that the plasmon energies deduced from the Auger peaks change markedly with the Sn content in these glasses. These results are consistent with the fragmentation of the molecular cluster network model proposed by Mikrut and McNeil. DOE

CRC CUSTOMER VERSUS RATER OCTANE NUMBER REQUIREMENT PROGRAM (1990)
Oct. 1993 127 p
(AD-A273997; CRC-586) Avail: CASI HC A07/MF A02

A CRC cooperative program was conducted to determine the difference in octane requirements between technical raters and 'customers' (the general driving public). The tests were conducted in two phases, with the second being a repeat of the first to verify the results obtained. The trained raters used the CRC E-15 procedure to determine the octane requirement of the vehicles while the customers' perception and objection to knock were determined through the use of a questionnaire. The customers' responses (perception and objection level) were based upon audible knock, acceleration performance, and after-run on a series of full-boiling-range customer/rater unleaded (FBRCU) reference-fuels. Data were analyzed from 168 1988-1991 model-year vehicles, with 126 of these tested in Phase 2. The results showed that the customers, objections, and perceptions were overwhelmingly based on knock, rather than acceleration performance or after-run. Two general methods, a population comparison and a delta analysis, were used to estimate the difference between customer and rater octane requirements. In the first method, the data were analyzed by comparing satisfaction curves for the technical and customer octane requirements (population comparison). DTIC

A MATERIALS COMPATIBILITY STUDY IN FM-1, A LIQUID COMPONENT OF A PASTE EXTRUDABLE EXPLOSIVE
S. H. Goods, T. J. Shepodd, B. E. Mills, and P. Foster (Mason and Hanger-Silas Mason Co., Inc., Amarillo, TX.) Sep. 1993 27 p
(Contract DE-AC04-76DR-00789)
(DE94-001166; SAND-93-8237) Avail: CASI HC A03/MF A01

The chemical compatibility of various metallic and organic containment materials with a constituent of a paste extrudable explosive (PEX) has been examined through a series of long-term exposures. Corrosion coupons and mechanical test specimens (polymers only) were exposed to FM-1, a principal liquid component of PEX, at 74 C. The LLNL designator for this formulation is RX-08-FK. Compatibility was determined in the following manner: by measuring changes in weight, physical dimensions, and mechanical properties; by examining the coupons for discoloration, surface attack, and corrosion products; and by analyzing for dissolved metals in the FM-1. Of the metals and alloys examined, none of the 300 series stainless steels exhibited adequate corrosion resistance after 74 days of exposure. Copper showed evidence of severe uniform surface attack. Monel 400 also exhibited signs of chemical attack. Nickel and tantalum showed less evidence of attack, although neither was immune to the liquid. Gold coupons developed a 'tarnish' film. The gold along with an aluminum alloy, 6061 (in the T6 condition) performed the most satisfactorily. A wide range of polymers were tested for 61 days at 74 C. The materials that exhibited the most favorable response in terms of weight change, dimensional stability, and mechanical properties were Kalrez, PTFE Teflon, and polyethylene. DOE

NATURAL GAS APPLICATIONS FOR HYBRID VEHICLES. Final Report, Oct. 1992 - Jul. 1993
Jeffrey M. Bentley Aug. 1993 68 p Sponsored by Gas Research Inst., Chicago, IL
(PB94-117108; Rept-41377; GRI-93/0266) Avail: CASI HC A04/MF A01

Hybrid vehicle technology holds the potential for improved efficiency and emissions compared with internal combustion (IC) engines and improved range and refueling convenience over electric vehicles. This study evaluated the potential for using natural gas as a hybrid vehicle fuel. Potential regulatory and market drivers were evaluated for hybrids generally and natural gas hybrids in specific. Heat engine options and other configuration issues were investigated to determine efficiency, emissions, or other benefits of light- and heavy-duty hybrids. Several hybrid vehicle configurations were evaluated to determine the specific packaging attributes of natural gas in a hybrid configuration. Generally, conventional IC engines appear adequate for most emissions-sensitive hybrid applications with no great advantage being gained from using turbines or other more advanced heat engines. The largest technology barrier to a near-term hybrid is the weight of available or near-term batteries. Smaller, light-duty hybrid vehicles will be more sensitive to this weight handicap than larger vehicles such as the urban transit bus. NTIS

CRYOGENIC SIZE REDUCTION OF SOLID PROPELLANT Final Report
Will P. Creedon and Michael H. Spritzer Mar. 1993 115 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A274844; ESL-TR-92-30) Avail: CASI HC A06

A growing need exists to develop improved methods for the disposal and/or recovery of solid rocket propellants. Laboratory, bench-scale, and prototype tests were performed to develop the dry washout concept for size reduction and removal of solid propellants using cryogenic media. Three propellant types were investigated: Hazard Class 1.1 composite modified double base (CMDB), Hazard Class 1.1 cross-linked double base (XLDB), and Hazard Class 1.3 hydroxl terminated polybutadiene (HTPB). No propellant initiations were detected. The laboratory tests established that essentially no change in the sensitivity of the test propellants occurs between ambient and cryogenic temperature. Impact, friction, low-level shock, and electrostatic discharge sensitivity tests were conducted. Over 2000 trials were conducted. The bench-scale tests demonstrated the safety of liquid nitrogen washout and established parameter ranges for effective propellant removal. Removal rates of greater than 60 pounds per hour were achieved for all propellant types. The prototype tests demonstrated cryogenic washout of several reduced scale motors in a semiautomated process. Two motors were processed, one containing 40 pounds of XLDB propellant, the other containing 60 pounds of HTPB propellant. Propellant removal rates ranged from 8.3 pounds per hour to 156 pounds per hour with liquid nitrogen flow of less than 4 gpm. DTIC

FEASIBILITY STUDY ON INTRODUCTION OF TRANSPORTATION-USE PETROLEUM SUBSTITUTION ENERGY
Mar. 1993 112 p In JAPANESE Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-725205; NEDO-P-9225) Avail: CASI HC A06

As a part of the development of petroleum substitution energy, development of vehicles using petroleum substitution fuel has been promoted to meet a need for abating pollution caused by automobile exhaust gas in cities. This investigation is first made on the trends of making the existing cars low-pollutant, of policies for wide use/promotion of substitution fuel cars, and of possession of vehicles. It is then made on assumption of future performance and cost of electric vehicles, methanol cars and CNG cars through hearing on expert opinions from makers, promotion organizations, etc. Based on the assumption, shares of existing cars and petroleum substitution cars in newly registered cars are set up in time sequence, and a built simulation model for wide spread estimates the number of vehicles which can be spread by 2010. The result shows the number of vehicles to be spread is 380,000, and it is lower than those targeted and predicted by industry-associated organizations. For wide spread, it is important to select suitable markets for substitution fuel cars as promotion targets. DOE

PRESENT SITUATION OF THE DEVELOPMENT OF PETROLEUM SUBSTITUTION ENERGY (FRANCE)
Mar. 1993 47 p In JAPANESE Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-725201; NEDO-P-9206) Avail: CASI HC A03

Survey is made to grasp the developmental trend of petroleum substitution energy in France. Since EC's market integration in 1993, France has been forced to change its energy policy to EC rules and has attempted opening the domestic market and strengthening the international competitiveness, taking measures such as adoption of the act on the internationalization of open tenders for public works. The petroleum industry requires a capital investment which is 5 billion francs annually or 45 billion francs in total through 2000 to cope with regulations related to petroleum industry wastes. The industry circle is against the carbon tax proposed by the EC commission, and companies in the petroleum industry are going ahead with their own environmental measures. The government is expected to make an increase in tax on petroleum products which amounts to 1.5 billion francs in fiscal 1993. However, the petroleum industry is in bad shape. The move toward promotion of the use of substitutional fuels using agricultural products as raw materials has been intensifying. Reduced dependence on nuclear power and introduction of substitutional fuels are proposed; however, Electricite de France makes an upward revision of nuclear power plant construction projects. The conventional nuclear power generation promotion line will be maintained together with diversification of energy sources, energy conservation, and environmental policies. DOE

UNCERTAINTIES IN THE CHARACTERIZATION OF THE THERMAL ENVIRONMENT OF A SOLID ROCKET PROPELLANT FIRE
J. C. Diaz Oct. 1993 6 p Presented at the 2nd Probabilistic Safety Assessment and Management Conference, San Diego, CA, 20-24 Mar. 1994
(Contract W-7405-eng-48)
(DE94-002023; UCRL-JC-113809; CONF-940312-25) Avail: CASI HC A02/MF A01

There has been an interest in developing models capable of predicting the response of systems to Minuteman (MM) 3 third-stage solid propellant fires. Input parameters for such an effort include the boundary conditions that describe the fire temperature, heat flux, emissivity, and propellant burn rate. In this study, scanning spectroscopy and pyrometry were used to infer plume temperatures. Each diagnostic system possessed strengths and weaknesses. The intention was to use various supportive methods to infer plume temperature and emissivity because no one diagnostic had proven capabilities for determining temperature under these conditions. Furthermore, these diagnostics were being used near the limit of their applicability. All these points created some uncertainty in the data collected. DOE

THE ADDITION OF MOLECULAR OXYGEN TO HYDROPEROXY-PROPYL RADICALS
Joseph W. Bozzelli (New Jersey Inst. of Tech., Newark.) and William J. Pitz Oct. 1993 25 p Presented at the Fall Meeting of the Western States Section of the Combustion Institute, Menlo Park, CA, 18-19 Oct. 1993
(Contract W-7405-eng-48)
(DE94-003662; UCRL-JC-115320; CONF-931076-4) Avail: CASI HC A03/MF A01

The addition of hydroperoxy-alkyl radicals to molecular oxygen is an important process leading to chain branching in the low temperature oxidation of paraffins and at conditions related to autoignition and engine knock. The product channels for the addition of hydroperoxy-propyl radicals to molecular oxygen were estimated using bimolecular QRRK analysis and transition state theory. Thermochemistry of all the relevant species was estimated using group additivity. The main products at 1 - 15 atm are stabilization, alkyl carbonyl + OH, and in some cases an olefinic hydroperoxide + HO2. Product channels for each of the three hydroperoxy-alkyl isomers were analyzed, and rate expressions for each channel were calculated for a series of pressures over a temperature range of 600 - 1600 K. The driving purpose of this document is to clarify technical facts that have been brought up by the findings and recommendations of the Drell report. Some of the findings and recommendations have been seriously challenged. The technical matters discussed in this report are intended to clarify some issues and misunderstandings. They are as follows: (1) detonation threshold (SDT or DDT) of Insensitive High Explosive (IHE) vs. conventional PBX nuclear warhead explosive (2) relative ignitability of Class 1.1 vs. Class 1.3 propellants; (3) magnitude of near- and far-field damage by accidental explosion or detonation; and (4) operational range penalties incurred with missile modifications. Neither the safety of the fusing and firing of the nuclear weapon nor the propellant igniter system are dealt with here. Primarily our attention is centered on handling accidents pertinent to SLBM's; however, related hazards in some other systems that have relevance are addressed. Author (revised)

The Interface Configuration Experiment (ICE) was carried out on USML-1 to investigate liquid-gas interfaces in certain rotationally-symmetric containers having prescribed, mathematically derived shapes. These containers have the property that they admit an entire continuum of distinct equilibrium rotationally-symmetric interfaces for a given liquid volume and contact angle. Furthermore, it can be shown that none of these interfaces can be stable. It was found, after the containers were filled in orbit, that an initial equilibrium interface from the symmetric continuum reoriented, when perturbed, to a stable interface that was not rotationally symmetric, in accordance with the mathematical theory. During a floating zone experiment involving the growth of indium on a recent orbiter mission, (STS 32) oscillation of the zone shapes were observed to occur in response to the background acceleration. An understanding of the nature of the response of the zone shape to forced (g-jitter) oscillations and predictions of its impact on future experiments is of great interest not only to the PI's but to other commercial and academic investigators who plan to fly similar experiments in the orbiter and on space station. Motivated by this, a 15 month study was undertaken to analyze the nature of the g-sensitivity of the STS 32 floating zone crystal growth experiment. Numerical models were used to describe the time-dependent free surface motion of the zone as it responds to the spacecraft residual acceleration. Relevant experimental data concerning the acceleration environment was obtained from the Honeywell in Space Accelerometer (HISA) investigators through MSFC's ACAP program and processed and analyzed. For the indium floating zone experiment, a series of calculations were made using time-dependent axial accelerations g(t). The form of g(t) included simple sinusoidal disturbances as well as actual data (subject to appropriate filtering) measured on the STS 32 mission. Focus was on the calculation of the response of the free surface of the zone as well as the internal flows and internal heat transfer. The influence of solidification on the response of the zone shape was also examined but found to be negligible. Author (revised)

(JTN-94-80579) Avail: CASI HC A04/MF A01

The following were studied in microgravity: (1) welding phenomena; (2) fluid behaviors; and (3) truss structure attenuation properties. The following results were obtained: (1) welding experiments turned out to be possible to conduct in precipitation tower facilities; (2) in the basic studies utilizing differences in surface tensions by temperature slopes, data identical to theoretical formulae were obtained, proving the effectiveness of forecast by the formulae. In the experiment of specific periods for sloshing, it was found that basic dimensional sloshing was instantly generated but it did not sustain, and that high-dimensional sloshing waves were also generated on free surfaces but they attenuated pretty soon. Considerably large sloshing waves generated were important for calculation of dynamic pressure applied to vessels. And (3) data obtained on vibration/amplitude ratio in drop tests in microgravity were quite similar to those obtained under simulated non-gravity environment. The amount of play affected vibration behaviors in simulated non-gravity, but it had no effects in normal gravity. Subtle differences in supporting points affect vibration behaviors in both normal and simulated non-gravity environments. Author (NASDA)

SPACE EXPERIMENTS WITH PARTICLE ACCELERATORS (SEPAC) Final Report, 29 Sep. 1992 - 31 Dec. 1993
William W. L. Taylor 9 Feb. 1994 102 p
(Contract NAS8-39569)
(NASA-CR-193935; NAS 1.26:193935) Avail: CASI HC A06/MF A02

The scientific emphasis of this contract has been on the physics of beam ionosphere interactions, in particular, what are the plasma wave levels stimulated by the Space Experiments with Particle Accelerators (SEPAC) electron beam as it is ejected from the Electron Beam Accelerator (EBA) and passes into and through the ionosphere. There were two different phenomena expected. The first was generation of plasma waves by the interaction of the DC component of the beam with the plasma of the ionosphere, by wave particle interactions. The second was the generation of waves at the pulsing frequency of the beam (AC component). This is referred to as using the beam as a virtual antenna, because the beam of electrons is a coherent electrical current confined to move along the earth's magnetic field. As in a physical antenna, a conductor at a radio or TV station, the beam virtual antenna radiates electromagnetic waves at the frequency of the current variations. These two phenomena were investigated during the period of this contract. Derived from text

Development of new functional materials is vitally important in science and technology in the next century. Space can be utilized for investigating or fabricating new functional materials from the following three viewpoints: investigation of the materials that can be practically used in space, including those for space rockets, space satellites, and space stations; utilization of space as a material research laboratory where advanced technologies for fabricating materials can be learned under precise control on an atomic scale; and production of materials and devices of high utility in terms of performance, quantity, and size by taking advantage of the features of space such as microgravity, high vacuum, vast space, and plenty of solar energy. The effectiveness of expensive research in space could be justified from the following standpoints: to fabricate materials in space and use them in space; to fabricate materials in space and transport them to the earth; and to just forget about a direct economic payback with an expectation of a dramatic progress in material science in the future, resulting from fundamental research in space. DESIGN OF COLD-FORMED HSS CHANNELS FOR BENDING AND ECCENTRIC COMPRESSION: BENDING IN THE PLANE OF SYMMETRY
Asko Talja Oct. 1992 96 p Sponsored by Technology Development Center of Finland; Rautaruukki Oy, Finland; Ministry of Environment, Finland; TE-EM Oy, Finland; Aaro Kohonen Oy, Finland; Magnus Malmberg Oy, Finland; and Juva Engineering Ltd., Finland
(VTT-TIED-1403; ISBN-951-38-4217-7; ETN-94-95250) Copyright Avail: CASI HC A05/MF A01

Open channel sections manufactured from High Strength Steels (HSS) were tested. The sections were bent in the plane of symmetry of the cross sections. The roll formed test profiles, one double U, two C and two hat profiles with yield stress of 560 to 670 N/sq mm and material thickness of 4 to 6 mm were taken from normal production. The buckling of plates or edge stiffeners was observed in some profiles. Tests for bending, eccentric compression and concentrated load were made. The test results together with other tests results from literature are compared with the design resistances determined according to the proposed design method. The method is satisfactory for normal design, but in some cases it was found to be too conservative. Comparisons with the other test results confirmed that the accuracy of the design rules do not depend on the yield strength or wall thickness. ESA

SAFETY ANALYSIS IN CONCEPTUAL DESIGN OF PROCESS CONTROL Ph.D. Thesis - Tampere Univ.
Arja Toola Oct. 1992 101 p Sponsored by Finnish Work Environmental Fund, and City of Tampere Scientific Foundation, Finland
(ISSN 1235-0621)
(VTT-PUBS-117; ISBN-951-38-4235-5; ETN-94-95233) Copyright Avail: CASI HC A06/MF A02

The conceptual design of process control systems, and the problem of safety requirements determination are investigated. Safety analysis methods of process design are applied. A two phase method Safe Control Requirements Analysis Method (SCRAM) was applied for analyzing the safety aspects of large processes within reasonable time. The first phase studies potential accidents on the basis of materials handled in the process circumstances. The second phase studies ways in which the process is led to unsafe states and how accidents may subsequently develop. The basic idea is to find the hazardous states of the process, the critical process parameters, and the accident chains. The desired operating conditions and parameters to be controlled are determined. The results show that the method identifies safety critical parameters and control actions and can be used for control system designers' purposes. ESA

The aim of the research was to investigate the effectiveness of capital investment, particularly investment in Advanced Manufacturing Technology (AMT). AMT encompasses not only production, but also design and administration areas. The intention was to make recommendations for the future direction of investment in the industry. The structure of the industry which comprises 54 companies is outlined. In order to obtain sufficiently detailed and accurate data, each company was visited. Discussions were held with managers covering the areas of production, engineering, finance, design, sales and marketing, quality and other strategic issues affecting investment decision making. The study conclusions and recommendations are presented. An overview of the industry and the survey sample are given. Company performance, practice relationships which link practice, and performance are discussed. ESA

FIRE SIMULATION BASED ON CONVECTION CALCULATION [VIRTAUSLASKENTAAN PERUSTUVA TULIPALOJEN SIMULOINTI]
Risto Huhtanen and Tommy Jacobson Oct. 1992 51 p In FINNISH
(ISSN 1235-0605)
(VTT-TIED-1411; ISBN-951-38-4305-X; ETN-94-95271) Copyright Avail: CASI HC A04/MF A01

Fire simulation based on the convection calculation is described, and the result is compared to results obtained from a fire test carried out in an abandoned nuclear station. In the simulation, the convection field of the whole building is described, as well as the structures and extreme conditions affecting it. The fire is described as a data source whose value varies with time. The heat transmission in the structures is described using a separate heat transfer program. The result correctly describes the convection and temperature field caused by the fire. A 'discrete-transfer' method for calculating the heat radiation, progressing obliquely in relation to the calculation network, is given. ESA

A project to evaluate and improve the work accident inquest system TOT (Finnish acronym) is reported. The study began with visits to workplaces where mortal accidents had occurred. Inquest reports, accident information dissemination, and the use of inquest reports, were examined. The study showed that work-related accidental deaths had a warning value, due to the gravity of the event, that could be exploited in the prevention field. The inquest system was shown to operate stably, all elements operating at least satisfactorily, and no improvement objective could be distinguished as more urgent than another. Improvement possibilities in the general system operation and in the capacity of workplaces to use inquest reports were shown. ESA

THE MICROSTRUCTURAL RESPONSE OF GRANULAR SOIL UNDER UNIAXIAL STRAIN Final Report, Sep. 1990 - Nov. 1992
John J. Gill Oct. 1993 112 p
(AD-A274808; PL-TR-92-1064) Avail: CASI HC A06/MF A02

Soil mechanical behavior is described and phenomenological (macroscopic) and microstructural (particulate) theories, developed to predict the constitutive response of granular media, are discussed. Special emphasis is given to the concept of fabric in granular media and how the concept relates to observed mechanical behavior. This report describes an experimental effort to quantify changes which occur in a cuboid specimen of granular silica material under uniaxial strains of up to 10 percent. The material tested was a poorly graded ottowa sand with specimens consisting of either 0.5- or 0.75-mm-diam. granules. The displacement fields perpendicular to the loading axis are generally not directly proportional to applied macroscopic strain as typically predicted by a local theory. Rather, the three 'zones' existing in a specimen under uniaxial strain are (1) a zone in which relatively high local displacements (and strain) occur (near the loading cap), (2) a zone behind this 'front' wherein the grains move directly in relation to the advance of the loading cap, and (3) a zone which has not yet responded to the advancing cap. Sidewall friction, although not negligible, appears not to play an overriding role in the grain micromotions. DTIC

THE PROLIFERATION OF AEROSPACE WEAPONS TECHNOLOGY: BALLISTIC MISSILES AND THE CASE OF BRAZIL M.A. Thesis
Terrence John Vossen 13 Apr. 1993 147 p
(ISBN-0-315-84082-X; CTN-94-61050) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The rationale behind the development of ballistic missile production in Brazil is examined by exploring the political, military, and economic determinants of ballistic missile demand in that country. To ascertain how Brazil developed missile production capabilities, the contributions of aerospace industries in industrialized states, the Brazilian space program, trade between less-developed countries, and illicit trade in missile technology are assessed. It is argued that missile development increasingly became a function of economic as opposed to security considerations, and that technologies transferred from developed country aerospace firms and Brazil's space program were primarily responsible for the creation of production capabilities. It is also contended that the proliferation of missile technology to Brazil was consistent with the workings of a system evident in the aerospace weapons technology market that sustains the horizontal spread of weapons production capabilities. SUMMARIES OF BFRL FIRE RESEARCH IN-HOUSE PROJECTS AND GRANTS, 1993
Nora H. Jason Sep. 1993 230 p See also PB93-116390, 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-121050; NISTIR-5263) Avail: CASI HC A11

The report describes the fire research projects performed in the Building and Fire Research Laboratory (BFRL) and under its extramural grants program during fiscal year 1993. The BFRL Fire Research Program has directed its efforts under three program thrusts. The in-house priority projects, grants, and externally-funded efforts thus form an integrated, focussed ensemble. The publication is organized along those lines: fire risk and hazard prediction - carbon monoxide prediction, turbulent combustion, soot, engineering analysis, fire hazard assessment, and large fires; fire safety of products and materials - materials combustion, furniture flammability, and wall and ceiling fires; and advanced technologies for fire sensing and control - fire detection and fire suppression. For the convenience of the reader, an alphabetical listing of all grants is contained in Part 2.0. NTIS

The mission of the Fabrication Technology thrust area is to have an adequate base of manufacturing technology, not necessarily resident at Lawrence Livermore National Laboratory (LLNL), to conduct the future business of LLNL. The specific goals continue to be to do the following: (1) develop an understanding of fundamental fabrication processes; (2) construct general purpose process models that will have wide applicability; (3) document findings and models in journals; (4) transfer technology to LLNL programs, industry, and colleagues; and (5) develop continuing relationships with the industrial and academic communities to advance the collective understanding of fabrication processes. The strategy to ensure success is changing. For technologies in which they are expert and which will continue to be of future importance to LLNL, they can often attract outside resources both to maintain their expertise by applying it to a specific problem and to help fund further development. A popular vehicle to fund such work is the Cooperative Research and Development Agreement with industry. For technologies needing development because of their future critical importance and in which they are not expert, they use internal funding sources. These latter are the topics of the thrust area. Three FY-92 funded projects are discussed in this section. Each project clearly moves the Fabrication Technology thrust area towards the goals outlined above. They have also continued their membership in the North Carolina State University Precision Engineering Center, a multidisciplinary research and graduate program established to provide the new technologies needed by high-technology institutions in the U.S. As members, they have access to and use of the results of their research projects, many of which parallel the precision engineering efforts at LLNL. CALCULATIONS OF MATERIAL REMOVAL, REMOVAL RATE, AND PRESTON COEFFICIENT IN CONTINUOUS LAPPING/POLISHING MACHINES
P. P. Hed 18 Oct. 1993 9 p
(Contract W-7405-eng-48)
(DE94-002619; UCRL-ID-115321) Avail: CASI HC A02/MF A01

Lapping and polishing machines usually do not have deterministic model to pre-determine removal rate and total material to be removed. The removal process is mainly affected by relative motion between the lap and the substrates, by load applied, and by mechano-chemical characteristics of the substrate material, as well as the abrasive and lap materials. Therefore, frequent measurements of the removal is necessary. This paper, written for optical technicians, includes formulas to calculate material removal from mass loss and removal rate from mass loss during operation. Establishing the removal rate helps by reducing the frequency of intermediate thickness measurements. The paper also includes the calculation of Preston coefficient, which is a measure of lapping process efficiency. DOE

PHYSICAL MODELLING AND ADAPTIVE PREDICTIVE CONTROL OF DIFFUSION/LPCVD REACTORS Ph.D. Thesis
H. deWaard 22 Dec. 1992 285 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-126398) Avail: CASI HC A13

The aim of this study is to design a temperature controller for batch electric diffusion/low pressure chemical vapor deposition (LPCVD) furnaces, that complies with the increasingly more stringent requirements of VLSI processing. A mathematical model has been developed for batch electric diffusion/LPCVD reactors that are currently used in the semiconductor industry for the fabrication of micro-electronic devices. The model has been formulated in terms of partial integro-differential equations, which are derived from the basic energy conservation law of physics. The model takes into account the effects of radiation and conduction. Chapter 2 gives a detailed description of the furnace system and provides some insight into the processes that take place. In chapter 3, the model of the diffusion/LPPCVD furnace is derived. Chapter 4 deals with the design of a temperature control system for the diffusion/LPCVD reactor, that makes use of the model as developed in chapter 3. Chapter 5 gives the results of the control designs, both of simulation and of application on a real furnace. Results of the linear quadratic Gaussian controller, the (non-adaptive) reduced order controller, and the adaptive predictive controller are presented. Finally, in chapter 6, some conclusions are drawn and suggestions for further research are given. NTIS

AUTOMATED IN-SITU INSPECTION SYSTEMS FOR UNDERGROUND STORAGE TANKS Final Technical Report, 16 Aug. - 29 Dec. 1993

Chris C. Fromme and Warren C. Whittaker 29 Dec. 1993 35 p
(Contract DACA88-93-C-0008)
(AD-A274644; Rept-9224-RPT-004.1) Avail: CASI HC A03/MF A01

The Army-has 20,000 underground fuel storage tanks (UST's) that must be brought into compliance with the new federal regulations by 1998. To be compliant, a tank must be closed, upgraded or replaced. This report covers the investigative research for the development of a robotic system capable of performing an in situ ultrasonic thickness inspection on the interior of a fueled UST. The robotic system is designed to meet the criteria outlined in the Draft Standard for the Robotic inspection of Underground Storage Tanks developed for the EPA. This robotic inspection will allow the Army to make an informed decision on the appropriate action to be taken for a given tank. The robotic system offers a cost effective way to monitor a tank when compared with the existing manual technology that produces the same results. The robotic technology also moves the human out of the UST which eliminates the human liability factor in the hazardous environment. DTIC

RECENT TREND OF DOMESTIC AND INTERNATIONAL REGULATIONS ON INTACT STABILITY OF SHIPS FOR SAFETY [SENPAKU NO ANZENSEI TO HI SONSHOJI FUKUGENSEI KISOKU NO SAIKIN NO DOKO]

Yasuyuki Yamakoshi *In its* Technical Report of National Research Institute of Fisheries Engineering: Fishing Boat and Instrument, No. 12 25 Mar. 1992 p 1-32 In JAPANESE (For primary document see N94-27976 07-31)
Avail: CASI HC A03/MF A01

It is important to develop an adequate regulation or standard for ships from a viewpoint of safety of life and ship at sea. The present report deals with recent trend of domestic and international regulations or standards on intact stability of ships with special attention to the activity of IMO (International Maritime Organization) and domestic standards of intact stability of ships established after 1986. Recently the importance of development of the rational regulations on intact stability of ships based on physical grounds has been recognized. Therefore, an advanced research for safety of life and ship at sea should be required. Author (NASDA)

E. H. P. ESTIMATION OF HIGH SPEED FISHING BOATS BY SOME EXISTING METHODS [KOSOKU ENGAN GYOSEN NI TAISURU BARIKI SUITEIHO NO TEKIYO NI TSUITE]

Toshikazu Masuya *In its* Technical Report of National Research Institute of Fisheries Engineering: Fishing Boat and Instrument, No. 12 25 Mar. 1992 p 33-42 In JAPANESE (For primary document see N94-27976 07-31)
Avail: CASI HC A02/MF A01

In recent years, the speed of coastal fishing boats are increasing up to 1.0 or more in Froude number. So the designers of fishing boats require the development of the estimation methods of EHP (Effective Horse Power) in high Froude number. Therefore, in this report, some existing methods are examined for the estimation of EHP on such high speed fishing boats by comparison with the results of the model experiments. Consequently, two methods show fairly good results. One is a formula by Radojcic and the other is a chart by Osumi-Kihara. Author (NASDA)

COMPUTER AIDED DATA RECORDING AND ANALYZING SYSTEM FOR THE ENGINE TEST [SHIKEN KIKAN NI OKERU DETA SHUROKU/KAISEKI SHISUTEMU]

Kenichi Oda and Katsuo Hasegawa *In its* Technical Report of National Research Institute of Fisheries Engineering: Fishing Boat and Instrument, No. 12 25 Mar. 1992 p 43-48 In JAPANESE (For primary document see N94-27976 07-31)
Avail: CASI HC A02/MF A01

This report describes computer aided data recording and analyzing system for the test engines in a laboratory. The system was developed for the purpose of recording and analyzing the engine data speedy and correctly. It is composed of two personal computers, A/D (Analogue to Digital)-converters and some measuring instruments. One of the computers functions as the analyzer of the low speed data, such as flow rate of fuel oil and several temperatures of the test engines; and another one functions as the analyzer of the high speed data, such as combustion pressure or vibration. These computers are connected with RS-232C interface, so researchers can control the system only to give the start command to the computer which treats low speed data. Author (NASDA)

THE EMISSION CHARACTERISTICS OF A HIGH SPEED DIESEL ENGINE [KOGATA DIZERU KIKAN NO NOKKUSU HAISHUTSU TOKUSEI]

Katsuo Hasegawa, Kenichi Oda, and Toshio Yamada *In its* Technical Report of National Research Institute of Fisheries Engineering: Fishing Boat and Instrument, No. 12 25 Mar. 1992 p 49-58 In JAPANESE (For primary document see N94-27976 07-31)
Avail: CASI HC A02/MF A01

The engine performances and the emission characteristics of a high speed diesel engine were experimentally investigated. The results indicate that NO(x) emission increases with a decrease in RPM (Revolution Per Minute) and increase of the inlet air temperature under the constant brake-mean effective pressures. It is very effective to delay the fuel injection timing for NO(x) emission reduction especially within the low speed range. NO(x) emission is influenced by temperature and pressure at the pre-mixed combustion. It also strongly depends on the cetane index of fuel. The NO(x) emission rate is closely related with the maximum pressure under specific operational conditions. Author (NASDA)

DEVELOPMENT OF SATELLITE TELECOMMUNICATIONS DURING THE PERIOD 1990 - 2005
D. Kumar Jan. 1993 60 p
(Cranfield-Aero-9301; ISBN-1-871564-56-5; ETN-94-95221) Avail: CASI HC A04/MF A01

The evolution of the global telecommunications market is reviewed. The changes that take place are a result of advances in technology as well as three powerful and interconnected forces: privatization, globalization, and liberalization. The introduction of new technologies in the form of Integrated Services Digital Networks (ISDN's) and integrated terminal equipment resulted in the transformation of the telecommunications services market from a single service industry limited by technology constraints into a multiservice industry limited by applications. As a result of privatization and globalization, the former national telecommunications carriers are beginning to expand overseas in order to grow. The changes indicate a shift in traffic structure as well as in the global satellite market structure. The analysis shows that satellite telecommunications will grow over the next fifteen years. ESA

EVALUATION OF AN ACOUSTIC CHARGE TRANSPORT (ACT) DEVICE FOR ADAPTIVE INTERFERENCE SUPPRESSION IN SPREAD SPECTRUM COMMUNICATIONS SYSTEMS M.S. Thesis
Michael S. Mills Dec. 1993 106 p
(AD-A274073; AFIT/GE/Eng/93D-27) Avail: CASI HC A06/MF A02

Analytical results have shown that adaptive filtering can be a powerful tool for the rejection of narrowband interference in a direct sequence spread spectrum receiver. However, the complexity of adaptive filtering hardware has hindered the experimental validation of these results. This thesis describes a unique adaptive filter architecture for implementing the Widrow-Hoff least mean square (LMS) algorithm using two state of the art acoustic charge transport (ACT) programmable transversal filters (PTF's). Signal to noise ratio improvement measurements demonstrate the effectiveness of the adaptive filter for suppressing single- and dual-tone jammers at jammer to signal ratios (JSR's) of up to 30 dB. It is shown that the ACT adaptive interference rejection system can consistently produce 55 dB notch depths with 3-dB bandwidths as low as 300 kHz with minimal degradation to the spread spectrum signal. It is also shown that the adaptive system can eliminate single tone jammers at any frequency within the spread spectrum bandwidth at any of 10, 20, or 30 dB JSRs within 10 to 15 iterations of the adaptive algorithm. The only drawback with the adaptive system as tested is the amount of time taken to perform an iteration because of the requirement to update the PTF tap weights sequentially. Suggestions are given as to how this particular parameter of the adaptive interference system could be optimized. DTIC

COMPONENT CHARACTERIZATION AND DEVELOPMENT 2 Technical Report, Oct. 1991 - Dec. 1992
Jacqueline D. Smith Sep. 1993 45 p
(AF Proj. 4600)
(AD-A274002; RL-TR-93-165) Avail: CASI HC A03/MF A01

The effort entitled, 'Component Characterization and Development II' was established in the Rome Lab Photonics Center Analog & Lightwave Photonics Branch as part of the overall in-house program plan to advanced the state-of-the-art in optics and electrooptics. The objective of the effort is to specify, acquire, and/or develop components for Air Force Command, Control, Communications, and Intelligence (C3I) applications. The source of prototype devices was designated to include academia, industry, and government organizations. Actual performance data was measured for both electro-optic and fiber-optic based devices that were of interest to communications, spatial laser control, and optical beamforming applications. Additionally, several novel approaches to device fabrication were investigated through a BAA contract with Syracuse University. DTIC

THE QUESTION OF STANDARDS FOR DIGITAL INTERACTIVE TELEVISION
Robert Thibadeau Nov. 1993 18 p
(Contract MDA972-92-J-1010; ARPA Order 6873)
(AD-A273872; CMU-RI-TR-93-23) Avail: CASI HC A03/MF A01

Pervasive change is near. Among the central elements of this change will be digital interactive television. It is generally thought that interactive television can have a profound beneficial impact on every element of the economy from average homeowner, to small and large business, and government agency. We have the opportunity now to engage public debate on what form interactive television should take. Should it come about as a series of private, mutually incompatible, insular systems, or should it be like television has traditionally been treated, subject to FCC standards akin to existing NTSC and the recently agreed HDTV standards. This article attempts to provide a framework for a broad discussion of such standards. DTIC

HYPERSPECTRAL ANALYSIS OF SPACE OBJECTS: SIGNAL TO NOISE EVALUATION M.S. Thesis
Daniel Hrovat Dec. 1993 154 p
(AD-A273882; AFIT/GSO/ENP/93D-02) Avail: CASI HC A08/MF A02

Hyperspectral analysis of space objects is being considered as a means of enhancing Space Object Identification (SOI) capabilities. This study develops a mathematical simulation based on fundamental radiometry principles to evaluate the feasibility of hyperspectral analysis of space objects. The study uses Signal to Noise Ratio (SNR) as the basis for the feasibility evaluation, and addresses the question: Is there enough target signal in narrow wavelength bandwidths to conduct hyperspectral measurements of space objects? The analysis characterizes the target signal and noise sources using fundamental radiometry, and develops a flexible radiometry model which calculates the target signal count rate, and SNR for a specified target-sensor configuration. The model was applied to four case studies, and revealed: (1) Enough target signal is present in narrow wavelength bandwidths for hyperspectral measurements; (2) Differences exist in signal strength as a function of wavelength and bandwidth which may serve as a basis for Space Object Identification applications. Hyperspectral analysis of space objects warrants further investigation. DTIC

EXTENSION OF ON-SURFACE RADIATION CONDITION (OSRC) THEORY TO FULL-VECTOR ELECTROMAGNETIC WAVE SCATTERING BY THREE-DIMENSIONAL CONDUCTING, DIELECTRIC, AND COATED TARGETS Final Report, 1 Jul. 1988 - 27 Aug. 1993
Allen Taflove and Korada R. Umashankar 27 Aug. 1993 253 p
(Contract N00014-88-K-0475)
(AD-A274023) Avail: CASI HC A12/MF A03

This project introduced radiation boundary condition (RBC) and absorbing boundary condition (ABC) theory to the engineering electromagnetics community. An approximate method for obtaining the scattering of 2-D and 3-D bodies, the on-surface radiation condition (OSRC) method, was formulated and validated. RBC's and ABC's were shown to work well at points closer to scatterers than anyone had expected. Finite-difference time domain (FD-TD) methods exploiting these ABC's were pursued for applications in scattering, radiation, penetration, biomedical studies, and nonlinear optics. Multiprocessing supercomputer software was developed for FD-TD, leading to the largest scale detailed electromagnetic wave interaction models ever conducted, including entire jet fighter aircraft modeled for radar cross section (RCS) at UHF frequencies up to 500 MHz. DTIC

ANALYZING ADAPTIVE BEAMFORMER PERFORMANCE IN A STABLE MULTIPATH ENVIRONMENT M.S. Thesis
Mark Godino Dec. 1993 91 p
(AD-A274029; AFIT/GE/ENG/93D-09) Avail: CASI HC A05/MF A01

Fighter aircraft equipped with X-Band radars having an adaptive beamforming capability exhibit degraded performance due to radome multipath reflection (RMR). The reflections from the radome into the antenna array degrade the pattern and cause the formation of large sidelobes. This phenomenon makes detection of LO targets difficult when jamming enters the high RMR sidelobes. Actual radomes are curved and cause reflected wavefronts to be nonplanar. Analyzing beamformer performance under these conditions is difficult, since the beamformer response is defined as the amplitude and phase change experienced by a complex plane wave as a function of frequency and location. To work with planar wavefronts and for the sake of simplicity, we model the radome as two flat plates parallel to array broadside, one at each end of the array. This radome model demonstrates degraded beamformer performance by causing large sidelobes to form. This approximates the characteristics of the multipath environment caused by a real radome. The ability of a linearly constrained, minimum variance beamformer to cancel interference arriving in the sidelobes is evaluated. The cancellation performance depends on how many taps are employed and the source frequency bandwidth. Results are provided for a linear, equally spaced sixteen element array. DTIC

A METHOD FOR POPULATING THE KNOWLEDGE BASE OF APTAS, A DOMAIN-ORIENTED APPLICATION COMPOSITION SYSTEM M.S. Thesis
Raleigh A. Sandy, III Dec. 1993 130 p
(AD-A274034; AFIT/GCE/ENG/93D-13) Avail: CASI HC A07/MF A02

A formal process is described for populating the knowledge base of the Automatic Programming Technologies for Avionics Software (APTAS) system. This process was developed using a general knowledge base population process that applies to many knowledge-based software engineering systems. This general process is also described. The formal process for APTAS was demonstrated by storing new information from the radar tracking domain into the knowledge base of APTAS. Several procedures, some automatic and some manual, were implemented to support the formal process. DTIC

A STUDY OF TWO DIMENSIONAL TAPERED PERIODIC EDGE TREATMENTS TO REDUCE WIDEBAND EDGE DIFFRACTION M.S. Thesis
Russell A. Burleson Dec. 1993 226 p
(AD-A274054; AFIT/GE/Eng/93D-02) Avail: CASI HC A11/MF A03

This is a brief summary of a study to reduce diffraction from an infinite two dimensional edge using tapered periodic surfaces. The concept is to use the impedance characteristics of a periodic surface to create a tapered impedance; much like a tapered resistance commonly used for diffraction reduction. This approach has several advantages over tapered resistive treatments to include ease of fabrication, better engineering control of the impedance and negligible loss absorbed by the taper. In this study, four periodic tapers were design, built and tested. These tapers were also modeled using a variety of numerical techniques. The results from this study were quite promising. DTIC

ELECTROMAGNETIC PROPERTIES OF A TOROIDAL SOLENOID
G. N. Afanasev and V. M. Dubovik 1991 39 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-613032; JINR-E-4-91-425) Avail: CASI HC A03 (US Sales Only)

The electromagnetic properties of the toroidal solenoid with an alternate current are discussed. The multipole expansion for the electromagnetic field of the toroidal solenoid is obtained and the explicit expressions for the toroidal form factors and moments are given. Concrete realization of the current flowing in the solenoid's winding is presented. It is shown that the uniform rotation of the toroidal solenoid with a constant current in its winding leads to the appearance of the magnetic field outside the solenoid. DOE

DESIGN OF FOLDED WAVEGUIDE ANTENNA FOR ALCATOR C-MOD

C. H. Fogelman, T. S. Bigelow, M. D. Carter, D. J. Hoffman, B. W. Riemer, J. J. Yugo, S. N. Golovato (Massachusetts Inst. of Tech., Cambridge.), and P. Bonoli (Massachusetts Inst. of Tech., Cambridge.) 1993 4 p Presented at the Symposium on Fusion Engineering, Hyannis, MA, 11-15 Oct. 1993
(Contract DE-AC05-84OR-21400)
(DE94-003584; CONF-931018-65) Avail: CASI HC A01/MF A01

The Oak Ridge National Laboratory (ORNL) ion cyclotron range of frequencies (ICRF) antenna for Alcator C-Mod is a folded waveguide (FWG) antenna designed to determine whether the FWG can serve as a high power density, ceramic-free antenna for both present heating and fast wave current drive (FWCD) applications and for future tokamaks such as the International Thermonuclear Experimental Reactor (ITER) and the Tokamak Physics Experiment (TPX). The FWG is particularly attractive because it has a low internal electric field per unit power coupled to the Plasma. This results in more power capability and has been demonstrated by 1-MW (unloaded) tests on the Radio Frequency Test Facility (RFTF). The experiment will characterize the impact of an FWG on impurity control in the presence of high power density and on central beating. The antenna is designed to withstand the tokamak environment, including high heat fluxes, high-temperature bakeout, and major disruptions, without vacuum leaks. The front face is curved to fit the plasma outline. Two front plates are fabricated for the antenna one with full-width slits at every other location between vanes and the other with alternating right and left half-width slits at every location between vanes for pi-phasing. DOE

TWO DIMENSIONAL SELF-CONSISTENT FLUID SIMULATION OF RF INDUCTIVE SOURCES

G. DiPeso, V. Vahedi, D. W. Hewett, and T. D. Rognlien 17 Nov. 1993 19 p Presented at the 40th National Symposium of the American Vacuum Society, Orlando, FL, 15-19 Nov. 1993
(Contract W-7405-eng-48)
(DE94-003635; UCRL-JC-115684; CONF-9311104-13) Avail: CASI HC A03/MF A01

The two-dimensional (R-Z) electromagnetic code FMRZ was written tc model inductive sources self-consistently in time. The code models an argon plasma with momentum-transfer, excitation, and ionization as electron-neutral reactions and scattering and charge-exchange for the ion-neutral reactions. The electrons and ions are treated as Maxwellian fluid species and a reduced set of Maxwell's equations is used to advance the electromagnetic fields. The set of equations used in FMRZ is not subject to typical numerical constraints present in many time dynamic codes allowing one to choose appropriate time and space scales to resolve only the frequencies and scale lengths of interest. The model retains nonlinear driving terms which give rise to a pondermotive force that distorts the density profile. Density and power profiles will be used to illustrate the physical effects of various terms in the equations. Trends in average density and temperature compare well with an analytic model. DOE

N94-25950# Atmospheric and Environmental Research, Inc., Cambridge, MA.

A RESEARCH PROGRAM ON RADIATIVE TRANSFER MODEL DEVELOPMENT IN SUPPORT OF THE ARM PROGRAM

S. A. Clough 1 Oct. 1993 15 p
(Contract DE-FG02-90ER-61064)
(DE94-001146; DOE/ER-61064/3) Avail: CASI HC A03/MF A01

The objective of this research effort is to develop radiative transfer models that are consistent with ARM spectral radiance measurements for clear and cloudy atmospheres. Our approach is to develop the model physics and related databases with a line-by-line model in the context of available spectral radiance measurements. The line-by-line model then functions as an intermediate standard to both develop and validate rapid radiative transfer models appropriate to GCM applications. A preprint of an extended abstract for the 1994 AMS volume describing a Quality Measurement Experiment using the ARM spectral data is included as an attachment. DOE

ZERNIKE MOMENTS AND ROTATION INVARIANT OBJECT RECOGNITION. A NEURAL NETWORK ORIENTED CASE STUDY Final Report

P. F. Krekel Dec. 1992 88 p
(AD-A273749; FEL-92-A394; TDCK-TD-92-3840) Avail: CASI HC A05/MF A01

This report presents the results of the feasibility study investigating the characteristics of complex Zernike moments and their application in translation-, scale-, and rotation-invariant object recognition problems. The complex Zernike moments are used as characterizing features in a neural network based target recognition approach for the classification of objects in images recorded by sensors mounted on an airborne platform. The complex Zernike moments are a transformation of the image by the projection of the image onto an extended set of orthogonal polynomials. The emphasis of this study is laid on the evaluation of the performances of Zernike moments in relation with the application of neural networks. Therefore, three types of classifiers are evaluated: a multi-layer perceptron (MLP) neural network, a Bayes statistical classifier and a nearest-neighbor classifier. Experiments are based on a set of binary images simulating military vehicles extracted from the natural background. From these experiments the conclusion can be drawn that complex Zernike moments are efficient and effective object characterizing features that are robust under rotation of the object in the image and to a certain extent under varying affine projections of the object onto the image plane. THEORETICAL ASPECTS OF THE AGILE MIRROR Interim Report

Wallace M. Manheimer and Richard Fernsler 5 Jan. 1994 40 p
(AD-A274890; NRL/MR/6707-93-7425) Avail: CASI HC A03/MF A01

A planar plasma mirror which can be oriented electronically could have the capability of providing electronic steering of a microwave beam in a radar or electronic warfare system. This system is denoted the agile mirror. A recent experiment has demonstrated such a planar plasma and the associated microwave reflection. This plasma was produced by a hollow cathode glow discharge, where the hollow cathode was a grooved metallic trench in a Lucite plate. Various theoretical aspects of this configuration of an agile mirror are examined here. DTIC

DIRECT-CONVERSION-TO-BASEBAND FOR A NONLINEAR FM SIGNAL Memorandum Report
Ching-Tai Lin and Ben H. Cantrell 3 Jan. 1994 27 p
(AD-A274861; NRL/MR/5333-93-7437) Avail: CASI HC A03/MF A01

This report examines both nonlinear FM signals and a 'direct conversion to baseband' process in a radar application system. A phase predistortion function was generated which modifies the transmitted linear FM signal and synthesizes the desirable effect of a sidelobe weighting function. To avoid a mismatch in obtaining the in-phase and quadrature signal components at two separate processing channels, a low IF signal was directly converted to its baseband by a combination of sampling, filtering, and decimation. A band-limited nonlinear FM signal with a low pulse compression ratio is considered and processed. The compressed signal is also obtained through a pulse compression filter matched to the transmitted signal. DTIC

DETECTION OF TRANSIENT VECTOR-FIELDS IN ADDITIVE NOISE [DETEKSJON AV TRANSIENTE 3-DIMENSJONALE VEKTORSIGNALER MED ADDITIV STOEY]
Bent Groenvold 10 May 1993 80 p In NORWEGIAN
(FFI-93/7028; ETN-94-95212) Avail: CASI HC A05/MF A01

A method for detection of a passing ship using a single three axial magnetometer is proposed. The ship is approximated as a magnetic dipole, that makes a perturbation of the geomagnetic field at the sensor point during the passage. An analysis of the magnetic signals was carried out. A description of the ambient magnetic noise is given, and a model for the noise spectrum was chosen. The detection is done by a bank of matched filters, and a projection of the measures field vectors on to an expected field vector. The size of the filter bank is discussed, and computations are done to determine this. Simulations of the method were made to determine the gain in signal to noise ratio. ESA

ELECTRICAL ANALYSIS OF WIDEBAND AND DISTRIBUTED WINDOWS USING TIME-DEPENDENT FIELD CODES
C. C. Shang, M. Caplan, H. U. Nickel, and M. Thumm 16 Sep. 1993 4 p Presented at the 18th International Conference on Infrared and Millimeter Waves, Essex, England, 6-10 Sep. 1993
(Contract W-7405-eng-48)
(DE94-002987; UCRL-JC-114504; CONF-9309266-1) Avail: CASI HC A01/MF A01

Windows, which provide the barrier to maintain the vacuum envelope in a microwave tube, are critical components in high-average-power microwave sources, especially at millimeter wavelengths. As RF power levels approach the 100's of kWs to 1 MW range (CW), the window assembly experiences severe thermal and mechanical stresses. Depending on the source, the bandwidth of the window may be less than 1 GHz for gyrotron oscillators or up to approximately 20 GHz for the FOM Institute's fast-tunable, free-electron-maser. The bandwidth requirements give rise to a number of window configurations where the common goal is locally distributed heat dissipation. In order to better understand the transmission and RF properties of these microwave structures, the authors use detailed time-dependent field solvers. DOE

NUMERIC SOLUTION OF THE ELECTRIC FIELD INTEGRAL EQUATION USING GALERKIN'S METHOD FOR AXIALLY SYMMETRIC CASES Ph.D. Thesis - Tech. Univ. Graz
Klemens Lileg (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Oberpfaffenhofen, Germany.) Aug. 1993 139 p Transl. into ENGLISH of Numerische Loesung der elektrischen Feldintegralgleichung mittels Galerkin verfahren fuer axialsymmetrische Faelle (Oberpfaffenhofen, Germany, DLR) Dec. 1990 p 1-133 Original language document was announced as N91-30394
(ESA-TT-1264; DLR-FB-90-58; ETN-94-95287) Avail: CASI HC A07/MF A02

The electric field integral equation is solved for a cylindrical antenna with flat end caps using the method of moments. Trigonometric subdomain functions are used as basis functions; the weighting functions have the same shape as the basis functions (Galerkin's method). For the end caps, the approximation of the Numerical Electromagnetics Code (NEC) program is used; the excitation is due to a homogeneous field in a gap in the center of the antenna. The integrals to be calculated are evaluated precisely, numerically. The admittance thus calculated converges better than that calculated using NEC but in many cases it is not completely satisfactory. Therefore the approximate solution for the end caps is replaced with a more accurate calculation. Hemispherical end caps are introduced and trigonometric subdomain functions analogous to those used on the cylinder are used as basis functions. All additional calculations are evaluated without approximations again. Now the results for the admittance converge in all cases even for the small number of segments. The impedance was measured for a number of monopoles of various thicknesses; good agreement with the calculations is obtained for all frequencies. ESA

POLARIMETRIC INVESTIGATION OF EDGE SCATTERING BY MONO- AND BISTATIC MICROWAVE IMAGING
Wolfgang Herdeg (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Oberpfaffenhofen, Germany.) Aug. 1993 166 p Transl. into ENGLISH of Polarimetrische Untersuchung der Kantenstreuung in der mono- und bistatischen Mikrowellenabbildung (Oberpfaffenhoffen, Germany, DLR) Jul. 1991 p 1-153 Original language document was announced as N93-22656
(ESA-TT-1284; DLR-FB-91-32; ETN-94-95289) Avail: CASI HC A08/MF A02

The scattering of electromagnetic waves from edges in dependence on frequency, aspect angle, polarization, and bistatic angle is investigated. The edges of simple metal objects, namely cubes, plates, and wedges, are resolved in range and cross range using a high resolution microwave imaging process and are investigated as canonical structures. The Geometrical Theory of Diffraction (GTD) serves as the theoretical model. The scattering coefficients of the GTD are compared with experiment. The polarimetric results are presented using the Huynen parameters. In order to carry through bistatic measurements on a monostatic radar range, microwave mirrors are introduced. These are large metal plates which reflect the bistatic scatter contribution to the monostatic radar. Experimental results verify the proposed concepts. ESA

RADAR DETECTION OF LOW-ALTITUDE TARGETS IN A MARITIME ENVIRONMENT. VOLUME 2: METEOROLOGICAL AND RADAR DATA Final Report, Sep. 1989 - Sep. 1993
Kenneth D. Anderson Nov. 1993 172 p
(AD-A274658; NCCOSC/RDT/E-1630-Vol-2) Avail: CASI HC A08/MF A02

Results from a unique analytical and measurement effort to assess low-altitude short-range radar detection in an evaporation ducting environment validate propagation model predictions of reduced radar detection ranges within the radio horizon. Discrepancies between measured and predicted radar data demand a close examination of both meteorological data and surface layer theory. At ranges near and beyond the horizon, radar detection crucially depends both on the surface layer refractivity profile and on the adjacent mixed layer refractivity profile. An empirical model is described that merges the surface layer with the mixed layer forming a unified boundary layer. Other discrepancies, which are thought to be caused either by inadequate surface layer modeling (perhaps the moisture stability function) or by inadequate boundary layer meteorological measurements, suggest the need for improvements in surface layer modeling and new techniques to measure the refractivity structure. The combination of direct boundary layer (surface and mixed layer) meteorological measurements, remotely sensed radar measurements, and advanced numerical modeling capability provides valuable insight for a better understanding of the atmospheric boundary layer and its effects on the radar detection of low-altitude short-range targets. METHODS FOR IMPROVING LOW-ANGLE, LOW-ALTITUDE RADAR TRACKING ACCURACY M.S. Thesis
Ali Ozkara 23 Sep. 1993 69 p
(AD-A274914) Avail: CASI HC A04/MF A01

This thesis studies the problem of low-angle, low-altitude target tracking where the presence of multipath causes large angle errors. The problem is examined for a low sidelobe monopulse radar over a flat earth. A detailed multipath model is used to simulate the reflecting surface and the reflected signal is included in the monopulse processing simulation. Using this model the tracking error is obtained, and two multipath error reduction techniques are evaluated. The first method uses frequency agility to measure the angle over a wide frequency range. By averaging the results of many frequencies, the angle estimate can be significantly improved over that of a single frequency. The second method is referred to is difference beam phase toggling. By flipping the difference beam phase by 180 deg for two subsequent pulses, the return from a reflected path can be inside to cancel. DTIC

NEW BINARY INTEGRATION STRATEGIES AND CORRESPONDING R90 CALCULATIONS M.S. Thesis
Doo J. Kim 23 Sep. 1993 139 p
(AD-A274786) Avail: CASI HC A07/MF A02

Often to increase the probability of having a track that will not later be deleted by a radar some simple logic criterion is used. This thesis evaluates the performance of a new binary integration technique. This technique requires M hits out of N looks with x less than M hits being consecutive. Closed form expressions for the cumulative probability of detection are derived and Monte Carlo methods are used to verify the results. A significant increase in the cumulative probability of detection is shown to occur when this type of logic is imposed. Also derived are the corresponding confidence calculations on R60-R95 (a measure of radar performance defined as the range such that the cumulative probability of detecting an approaching target is 0.60-0.95) for each set of detections. AN EFFICIENT COMMUNICATION SCHEME FOR SOLVING THE S(SUB n) EQUATIONS ON MESSAGE-PASSING MULTIPROCESSORS
Y. Y. Azmy 1993 7 p Presented at the ANS Winter Meeting, San Francisco, CA, 14-18 Nov. 1993
(Contract DE-AC05-84OR-21400)
(DE94-000378; CONF-931160-19) Avail: CASI HC A02/MF A01

Early models of Intel's hypercube multiprocessors, e.g. the IPSC/1 and iPSC/2, were characterized by the high latency of message-passing. This relatively weak dependence of the communication penalty on the size of messages, in contrast to its strong dependence on the number of messages, justified using the Fan-in Fan-out algorithm to perform global operations, such as global sums, etc. Recent models of message passing computers, such as the iPSC/860 and the Paragon, have been found to possess much smaller latency, thus forcing a re-examination of the issue of performance optimization with respect to communication schemes. Essentially, the Fan-in Fan-out scheme minimizes the number of nonsimultaneous messages sent but not the volume of data traffic across the network. Furthermore, if a global operation is performed in conjunction with the message-passing, a large fraction of the attached nodes remains idle as the number of utilized processors is halved in each step of the process. On the other hand, the Recursive Halving scheme offers the smallest communication cost for global operations, but has some drawbacks. First, it requires the simultaneous exchange of messages between adjacent nodes, which while permissible on many message-passing computers, requires additional programming on the iPSC/860, the target platform in this work. Second, full utilization of the processors requires that the message length be a multiple of two, resulting in significant idleness of the processors if this is not the case. In this paper, we present an alternative scheme that eliminates the first drawback by communicating along a monodirectional ring, and reduces the impact of the second drawback by requiring only that the number of nodes divides the message length, a standard requirement for retaining load balance. DESIGN AND EVALUATION OF AN ELECTROMAGNETIC BEAM WAVEGUIDE FOR MEASURING ELECTRICAL PROPERTIES OF MATERIALS
M. C. Bailey Feb. 1994 32 p
(RTOP 505-64-52-04)
(NASA-TP-3418; L-17298; NAS 1.60:3418) Avail: CASI HC A03/MF A01

A beam waveguide was designed that is based upon the propagation characteristics of the fundamental Gaussian beam and the focusing properties of spherical dielectric lenses. The 20-GHz, two-horn, four-lens system was constructed and experimentally evaluated by probing the field in a plane perpendicular to the beam axis at the center of the beam waveguide system. The critical parameters were determined by numerical sensitivity studies, and the lens-horn critical spacing was adjusted to better focus the beam at the probe plane. The measured performance was analyzed by consideration of higher order Gaussian-Laguerre beam modes. The beam waveguide system was successfully used in the measurements of the electromagnetic transmission properties of Shuttle thermal-protection tiles while the tile surface was being heated to reentry-level temperatures with a high-power laser. THE APPLICATION OF FD-TD METHOD TO ANTENNA RADIATION PATTERNS M.S. Thesis
Qi Zhang Apr. 1992 105 p
(ISBN-0-315-83893-0; CTN-94-61036) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The finite difference time domain (FD-TD) method is applied to study antenna radiation patterns, especially those of array antennas, linear antennas, aperture antennas, and horn antennas. Several absorbing algorithms are reviewed and Reynolds' absorbing boundary is chosen for the FD-TD method due to its flexibility and simplicity for the numerical analysis. The accuracy of the FD-TD method in obtaining far-field patterns of various antennas is assessed. The numerical error caused by the finite mesh size of the FD-TD algorithm in the far field radiation pattern study is reduced. It has been recognized that the directional angle of the numerical wavefront is different from that of the physical wavefront. In the numerical simulation of the aperture and horn antennas, the amount of this shift can be predicted and is confirmed by the numerical results. A simple algorithm is developed to offset this shift and consequently the accuracy of the numerical results is improved. This algorithm will be very useful for future application of the FD-TD method in the far field antenna pattern study. In order to illustrate the capability of the FD-TD algorithm, several different types of antenna are analyzed. Wherever possible, most results are compared with the theoretical results and good agreements are found. Author (CISTI)

A ROUGH SET APPROACH TO SPEECH RECOGNITION M.S. Thesis
Zhigang Zhao Sep. 1992 93 p
(ISBN-0-315-83894-9; CTN-94-61037) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Speech recognition is a very difficult classification problem due to the variations in loudness, speed, and tone of voice. In the last 40 years, many methodologies have been developed to solve this problem, but most lack learning ability and depend fully on the knowledge of human experts. Systems of this kind are hard to develop and difficult to maintain and upgrade. A study was conducted to investigate the feasibility of using a machine learning approach in solving speech recognition problems. The system is based on rough set theory. It first generates a set of decision rules using a set of reference words called training samples, and then uses the decision rules to recognize new words. The main feature of this system is that, under the supervision of human experts, the machine learns and applies knowledge on its own to the designated tasks. The main advantages of this system over a traditional system are its simplicity and adaptiveness, which suggest that it may have significant potential in practical applications of computer speech recognition. Furthermore, the studies presented demonstrate the potential application of rough-set based learning systems in solving other important pattern classification problems, such as character recognition, system fault detection, and trainable robotic control. ANALYSIS OF LINEAR COMBINING AND ITS APPLICATION TO FREQUENCY-HOPPED SIGNALS Ph.D. Thesis
Rolands Eriks Ezers 3 May 1993 123 p
(ISBN-0-315-84007-2; CTN-94-61046) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A novel analytical method has been developed for obtaining performance for fast frequency hopped (FFH) noncoherent frequency shift keyed (NCFSK) communication systems employing linear diversity combining (LDC). The method combines circularly symmetric function theory, Fourier-Bessel series, and Fourier series. Performance measures are obtained for demodulation of FFH NCFSK systems with time diversity (TD) and LDC, and for the time synchronization of a FFH NCFSK satellite communication system with TD and LDC in broad-band noise and multiple tone jamming. Results using this method compare well to other reported results. A novel analytical result was also derived for computing the bit error probability for demodulation of FFH NCFSK systems with TD and 4-2- or 2-1-moment method diversity combining in independent Rayleigh fading with a diversity level of two. In a complete review of diversity combining techniques, the advantages and drawbacks of LDC under various noise, fading, and jamming conditions are discussed. For uplink coarse-time synchronization, TD and LDC could be used to improve performance. A binary NCFSK modulator and demodulator with TD and LDC was implemented in a hardware experiment, showing the viability and practicality of LDC. Author (CISTI)

IMPROVED PERFORMANCE OF HYBRID ERROR CONTROL TECHNIQUES FOR REAL-TIME DIGITAL COMMUNICATIONS OVER NOISY CHANNELS Ph.D. Thesis
Charlie Qing Yang 1993 196 p
(ISBN-0-315-84281-4; CTN-94-61019) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Delay-related performance characteristics are investigated for asynchronous time division multiplexing links. Two methods based on an imbedded Markov chain model are developed and applied to the system with a noisy feedback channel yielding analytical expressions for the buffer occupancy and the block delay. A recursive expression for packet loss probability for systems with a finite transmitter buffer is obtained. The concept of delay limited error control coding is introduced for real-time communications. Performance improvement by truncation of a type-2 hybrid automatic repeat-request (ARQ) protocol with one retransmission is examined showing that the truncated protocol has a bounded delay and bounded queue length under typical conditions. The error performance of the truncated protocol is further analyzed for various mobile fading channels. Matched rate hybrid error control coding for both adaptive and non-adaptive cases is also studied. A new adaptive error control protocol using Reed-Solomon codes is proposed using novel feedback transmissions to achieve faster estimation of channel states. Numerical optimization is carried out by introducing overall and modified throughput as efficiency criteria. Based on channel bit error rate measurement, optimum overall throughput is obtained with minimum implementation complexity. Author (CISTI)

ON THE PERFORMANCE OF TRELLIS CODED 8PSK WITH REED SOLOMON CODES M.S. Thesis
Yasuo Harada 1993 191 p
(ISBN-0-315-84289-X; CTN-94-61020) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Concatenated trellis-coded 8-ary phase shift keying (8PSK) with Reed Solomon (RS) codes is studied over additive white Gaussian noise and Rayleigh fading channels. Trellis coded modulation (TCM) achieves high coding gain without any bandwidth expansion. The basic analysis of its performance is reviewed and confirmed by simulation using a truncated Viterbi decoder. Trellis-coded 8PSK, which has an asymptotic coding gain of 3.6 dB, can be further improved by concatenation with RS codes. By concatenating TCM with an RS code, the bandwidth of the overall system is expanded by the reciprocal of the RS coding rate. Improvement in bit error rate performance is studied for this coding system with various combinations of RS codes. A code with a rate of 0.9 and a good bit error rate performance is chosen for further study for erasure and error decoding. Results suggest the performance can be improved with sufficient reliability of decoded symbols. The reliability of the input symbols to the RS decoder is obtained by a modified Viterbi decoder. Such a decoder is studied and the performance of the bit error rate is shown. To improve performance, a new, modified Viterbi decoder with averaged reliability information is proposed, and the bit error rate improvement is confirmed by computer simulation. Author (CISTI)

SPEECH CODING AT LOW TO MEDIUM BIT RATES Ph.D. Thesis
Wilfred Paul Leblanc 1 Sep. 1992 135 p
(ISBN-0-315-84012-9; CTN-94-61048) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Improved search techniques coupled with improved codebook design methodologies are proposed to improve the performance of conventional code-excited linear predictive coders for speech. Improved methods for quantizing the short term filter are developed by employing a tree search algorithm and joint codebook design to multistage vector quantization. Joint codebook design procedures are developed to design locally optimal multistage codebooks. Weighting during centroid computation is introduced to improve the outlier performance of the multistage vector quantizer. Multistage vector quantization is shown to be both robust against input characteristics and in the presence of channel errors. Spectral distortions of about 1 dB are obtained at rates of 22-28 bits/frame. Structured codebook design procedures for excitation in code-excited linear predictive coders are compared to general codebook design procedures. Little is lost using significant structure in the excitation codebooks while greatly reducing the search complexity. Sparse multistage configurations are proposed for reducing computational complexity and memory size. Improved search procedures are applied to code-excited linear prediction which attempt joint optimization of the short term filter, the adaptive codebook, and the excitation. Improvements in signal to noise ratio of 1-2 dB are realized in practice. Author (CISTI)

COMBATTING INHERENT VULNERABILITIES OF CFAR ALGORITHMS AND A NEW ROBUST CFAR DESIGN M.S. Thesis
Patrick J. Bowman Sep. 1993 158 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A274918) Avail: CASI HC A08

A current trend in radar technology is automatic detection and tracking systems. An integral part of these automatic systems is the constant false alarm rate (CFAR) detector. A CFAR detector is the signal process algorithm that controls the rate at which target detections are falsely declared. Given the current state of radar technology, CFAR algorithms are necessary elements of any automatic radar system. Unfortunately, CFAR systems are inherently vulnerable to degradation caused by large clutter edges, multiple targets, and jamming environments. This thesis presents eight popular and studied CFAR architectures. A comprehensive review of each system's structure, analysis, and performance is detailed. Also the performances of each CFAR processor are compared numerically for two different in-phase (I) and quadrature (Q) detectors: envelope approximation detector and the square law detector. In addition, each system is comprehensively compared to one another in the troublesome environments mention above. This thesis continues with the development of an original CFAR architecture, the excision greatest-of (EXGO). Although more complex, this processor is shown to be more robust than the other established techniques particularly in the presence of clutter edges, multiple targets, and electronic countermeasures (ECM) environments. USING THE TSAR ELECTROMAGNETIC MODELING SYSTEM

S. T. Pennock and G. W. Laguna Sep. 1993 41 p
(Contract W-7405-eng-48)
(DE94-002617; UCRL-ID-115227) Avail: CASI HC A03/MF A01

A new user, upon receipt of the TSAR EM modeling system, may be overwhelmed by the number of software packages to learn and the number of manuals associated with those packages. This is a document to describe the creation of a simple TSAR model, beginning with an MGED solid and continuing the process through final results from TSAR. It is not intended to be a complete description of all the parts of the TSAR package. Rather, it is intended simply to touch on all the steps in the modeling process and to take a new user through the system from start to finish. There are six basic parts to the TSAR package. The first, MGED, is part of the BRL-CAD package and is used to create a solid model. The second part, ANASTASIA, is the program used to sample the solid model and create a finite-difference mesh. The third program, IMAGE, lets the user view the mesh itself and verify its accuracy. If everything about the mesh is correct, the process continues to the fourth step, SETUP-TSAR, which creates the parameter files for compiling TSAR and the input file for running a particular simulation. The fifth step is actually running TSAR, the field modeling program. Finally, the output from TSAR is placed into SIG, B2RAS or another program for post-processing and plotting. Each of these steps will be described below. The best way to learn to use the TSAR software is to actually create and run a simple test problem. As an example of how to use the TSAR package, let's create a sphere with a rectangular internal cavity, with conical and cylindrical penetrations connecting the outside to the inside, and find the electric field inside the cavity when the object is exposed to a Gaussian plane wave. We will begin with the solid modeling software, MGED, a part of the BRL-CAD modeling release. DOE

S-76 HIGH INTENSITY RADIATED FIELDS, VOLUME 2 Final Report

Jerry Blair Oct. 1993 169 p
(AD-A274572; DOT/FAA/CT-93/5-Vol-2) Avail: CASI HC A08/MF A02

The Federal Aviation Administration (FAA) Technical Center sponsored a series of High Intensity Radiated Fields (HIRF) test on a Sikorsky S-76 rotorcraft. The project was conducted to evaluate the practically of performing aircraft level HIRF tests, determine the effects of HIRF on a specific rotorcraft with the potential to obtain information on rotorcraft in general, and evaluate the effects of exposure to real world HIRF emitters. HIRF ground and flight tests were conducted to achieve the objective of the project. Site calibration (SCAL) measurements were made in the test area to determine the levels at which the S-76 would be irradiated when placed in the test area. Ground tests consisted of Low Level Swept Coupling (LLSC) and Low Level Swept Fields (LLSF) tests. The flight tests were flown directly into the main beam of a variety of pulsed and continuous wave (CW) transmitters including the Over the Horizon Back Scatter (OTHB), PAVE PAWS, ASR-9, FPS-65, and FPS-16 radars. Results of the S-76 tests added credibility to the existence of HIRF as a flight safety hazard. In the evaluation of the emitters, the flight tests showed repeatable instances where exposure resulted in instrumentation disruptions. It should be noted that all the observed disruptions were of a non-critical nature. DTIC

COMPUTER PROGRAM FOR NUMERICAL EVALUATION OF THE PERFORMANCE OF AN OVERMODED TM01 CIRCULAR TO TE10 RECTANGULAR WAVEGUIDE MODE CONVERTER Final Report, Aug. 1991 - Aug. 1993

Joseph R. Mautz and Roger F. Harrington Dec. 1993 145 p
(Contract DAAL02-90-K-0027)
(AD-A274548; TR-93-1; ARL-CR-129) Avail: CASI HC A07/MF A02

Two identical rectangular waveguides are fed by means of two symmetrically placed apertures in a circular waveguide. Several modes can propagate in the circular waveguide but only the TE10 mode can propagate in the rectangular waveguides. The rectangular waveguides have identical dimensions but may be terminated with different loads. Power is transmitted from the propagating modes in the circular waveguide to the TE10 mode in each rectangular waveguide. A computer program was written to evaluate this power and the magnitude of each orthogonal component of the tangential electric field in the apertures. This program is obtained by modifying an existing program. The modifications are described and listed. Sample input and output data are provided. DTIC

Requirements from new applications, from mobility and from ATM have a significant impact on the development of signalling protocols for B-ISDN. One of the signalling protocols taking most of these requirements into account is EXPANSE. The EXPANSE protocol follows an object-oriented approach and separates calls from services (connections) and services form channels. This report gives a comprehensive example of using the EXPANSE protocol. NTIS

The presence of electromagnetic fields is in essence the cause of many interference problems in electric and electronic circuits. To analyze an interference problem, it is therefore essential to consider the electromagnetic field concept with its vectorial nature. Simple illustrations are: the emission of radiation by (short) wire segments (electric dipoles) and (small) loops (magnetic dipoles) and the susceptibility to radiation of such wire segments or loops in the near- or far-field regions and in the dependence on their orientation. INTERFERENCE ANALYSIS OF MULTICHANNEL TRANSMISSION LINES: A SYSTEM'S ANALYSIS
Adrianus T. deHoop and Dirk Quak 1993 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-126505; ET/EM-1993-17) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

In this chapter a system's description is presented of the interference analysis of multichannel transmission lines. A multichannel transmission line consists of a cylindrical configuration that is capable of guiding electromagnetic waves along its axial or longitudinal direction. The guiding structure may be composed of electrically conducting wires, electrically conducting strips, a conducting ground plane, and/or a number of optical communication fibers. It is assumed that the system's performance of the transmission line can be characterized by a finite number of discrete modes for which equivalent cross-sectional voltages and equivalent axial electric currents can be defined. In terms of these voltages and currents, the crosstalk and the influence of interfering external electromagnetic fields along the line can be analyzed. The associated array and matrix manipulations can be carried out with standard commercially available software. NTIS

AN ANALYSIS OF FM JAMMING AND NOISE QUALITY MEASURES M.S. Thesis
Timothy N. Taylor Dec. 1993 182 p
(AD-A274349; AFIT/GE/ENG/93D-38) Avail: CASI HC A09/MF A02

This thesis provides a description of FM-by-noise jamming, both at RF and at the output of the radar receiver, in terms of spectra, time-domain waveforms, and univariate probability density of amplitude. Particular emphasis is given to the case where the peak frequency deviation of the FM modulator is sufficiently small that Woodward's Theorem does not provide a good approximation of the RF spectrum. Additionally, noise quality measures which have been used to measure noise quality of radar jammers are considered theoretically and experimentally, and it is concluded that a noise measure which incorporates both a spectral measure and a probability density measure should be adopted. One such measure is proposed here. Lastly, a technique for measuring the noise quality of an operational jammer is demonstrated and the programs necessary to measure noise quality of an operational jammer are included here. DTIC

ENCODING APPROACHES FOR DATA LINK TRANSMISSION OF WEATHER GRAPHICS
Jeffrey L. Gertz and Robert D. Grappel 10 Dec. 1993 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts DTFA01-93-Z-02012; F19628-90-C-0002)
(AD-A274497; ATC-205; DOT/FAA/RD-93/33) Avail: CASI HC A03

To provide pilots with necessary information to make informed decisions on the avoidance of hazardous weather and to maintain situational awareness of the weather conditions, the FAA is actively developing the capability to provide real-time graphical weather information to aircraft through the use of bandwidth-limited data links such as Mode S. The information content of weather images and the restricted bandwidth of the transmission channel require that the images be extensively compressed. This paper provides the results of a study concerning the applicability of various data compression algorithms to the weather image problem. Its conclusion is that the Polygon-Ellipse Algorithm developed at Lincoln Laboratory provides the best combination of compression, computational efficiency, and image quality for the encoding of weather images over the Mode S data link or other similarly bit-limited data links. EXPERIMENTS AND NUMERICAL SIMULATIONS OF ELECTROMAGNETIC WAVE PROPAGATION IN PLASMA VARYING RAPIDLY IN SPACE AND TIME Final Report, 1 Oct. 1992 - 30 Sep. 1993
S. P. Kuo 30 Sep. 1993 87 p
(Grant AF-AFOSR-0002-91)
(AD-A274376; AFOSR-93-0884TR) Avail: CASI HC A05/MF A01

In this work, the electromagnetic wave propagating in a fast growing plasma is studied experimentally and numerically. Theoretical models are developed to assist the numerical simulations. The plasma media involved in the study is classified into two categories: (1) the plasma density varies both temporally and spatially; (2) the plasma density is a function of time only. It is shown that the results of the numerical simulations based on the theoretical models agree well with those of the experiments. The agreement validates the developed theoretical models which can be used to guide and understand the future experiments on high power microwave pulse propagation and the future experiments for developing practical plasma devices. This study shows that the spectrum of a microwave will be modified while propagating through a fast growing plasma. DTIC

(Contract F49620-92-J-0378)
(AD-A274212; AFOSR-93-0902TR) Avail: CASI HC A02/MF A01

The researchers have separated the Kaiser-Teager algorithm for separating the contributions of the amplitude modulation and frequency modulation of a signal consisting of multiple components. To achieve this separation, they use an instantaneous non-linear operator, which turns out to be the determinant of a Toeplitz matrix formed with the signal samples. Because of its instantaneously adaptive nature, they can use this algorithm to track parameter variations that are not too rapid. The researchers demonstrate this using a synthetic signal containing two AM-FI4 signal components and a speech signal. They also point out the methods relationship to Prony's method. The researchers proposed a demodulator-filter approach for tracking harmonic signals and applied it to speech processing. DTIC

PROCESSING OF WIDE-ANGLE SYNTHETIC APERTURE RADAR SIGNALS FOR TARGET DETECTION M.S. Thesis

Kurt W. Knurr Dec. 1993 115 p
(AD-A274225; AFIT/GE/Eng/93D-22) Avail: CASI HC A06/MF A02

This study investigated methods of targets detection using Wide-Angle Synthetic Aperture Radar (WASAR). WASAR uses multiple aspect angle Synthetic Aperture Radar (SAR) images of the same scene. The SAR images were generated using a pre-release software package from package from Loral Corporation. The software was able to generate 512 by 512 pixel SAR images that contained various vegetation return which for our purposes we classified as clutter. Within this clutter, targets (M35 trucks) could be placed at random location and orientations. The software also had the capability of generating fully-polarimetic WASAR images with multiple depression angles. This data was then processed and various detection algorithms tested to exploit the amount and diversity of information available from the multiple images. SAR images are generally known to contain large amounts of data, and WASAR images contain even more due to the multiple images. Various pre-processing filters were analyzed for detection optimization. These filters included: polarimetric averaging, polarimetric span, polarimetric optimal weighting, and polarimetric whitening filters. Simple classical detection (thresholding) algorithms were evaluated using these preprocessed data sets. The use of WASAR imagery improved detection by allowing thresholds to be set higher than for simple SAR thereby avoiding false alarms yet still allowing detection of the known targets. DTIC

PERFORMANCE STATISTICS BULLETIN: HIGH ALTITUDE METEOR SCATTER PROPAGATION, AUGUST, SEPTEMBER, OCTOBER 1989 Interim Report

Alan D. Bailey, Jens C. Ostergaard, Regina M. Burton, Carlton H. Curtis, and Wayne I. Klemetti 7 Sep. 1993 218 p
(AF Proj. 4643)
(AD-A274455; PL-TR-93-2196; ERP-1129) Avail: CASI HC A10/MF A03

A representative sampling of meteor scatter propagation performance statistics is presented from the PL/GP High Latitude Meteor Scatter Test Bed. The data address questions of meteor scatter propagation under disturbed ionospheric conditions, as well as normal meteor scatter propagation in the polar region. The time and frequency variations of the propagation transfer function are characterized over the 35 to 147 MHz range, including the availability of useful meteor trails, the potential communication capacity associated with those trails, the occurrence and persistence of ionospheric scatter and sporadic E-layers, variations in the signal-to-noise ratios of each scatter return, and the effects of auroral and polar cap absorption (PCA) events on meteor scatter propagation and communications. Statistics covering Arrival Rate, Duration, Duty Cycle, and Noise Temperature are presented. This bulletin is one of a series of polar meteor scatter data bulletins. DTIC

OVER-THE-HORIZON PROPAGATION MEASUREMENTS AT SIX RADAR-FREQUENCY BANDS AT THE ATLANTIC OCEAN COAST

R. B. Boekema Jul. 1993 70 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A274151; FEL-92-B438; TDCK-93-0303) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In the autumn of 1989, the propagation subgroup of NATO AC/243 has conducted a propagation experiment near Lorient France, at the Atlantic Ocean. The purpose of this experiment was to gain an insight into the influence of the evaporation duct above the sea on the propagation of radar signals of different frequencies in an over-the-horizon situation and into the applicability of model predictions. The geometry of the experiment has been chosen to represent a typical ship defence situation. The measurements have shown that for the present case the nearly always present evaporation duct results in a signal enhancement with the strongest effects at the 10.5 and 16 GHz frequencies. An extended study of the quality of the model predictions, possible by the unique set of measurement results, shows some interesting matters. If the process of prediction is divided into two parts, the calculation of the duct height from the meteorological data and the path loss calculation from this duct height, the conclusion is made that the first part is responsible for the largest inaccuracies. The used duct height calculation method showed systematic deviations for different meteorological conditions. The inaccuracy of the duct height calculation makes useful path loss predictions at the millimeter-wave frequencies (35 and 94 GHz) impossible for this over-the-horizon situation. The predictions at the lower frequencies are much better, but not always satisfactory. The deviation analyses in this report can be useful to improve propagation models. DTIC

METHOD OF CORRECTING ROTATIONAL MOTION ERROR IN SAR AND ISAR IMAGERY Patent

Duane Roth, inventor (to Navy) 5 Oct. 1993 14 p Filed 1 Jul. 91
(AD-D016033; US-Patent-5,250,952; US-Patent-Appl-SN-727257) Avail: US Patent and Trademark Office

A method of correcting rotational motion error in SAR and ISAR imagery includes shifting the center of the image to zero doppler and thus to the center of rotation of the target being imaged, selecting a dominant scatterer at an off-center range cell to provide a phase reference, calculating the rotational motion error function from the phase of the selected scatterer, using the rotational motion error function to interpolate raw radar return image data between the original unequal angular samples to obtain equal angular samples of the target reflectivity function, and performing an image quality check and producing a value which is a relative measure of focus of the image. Also, the method includes repeating the steps starting with selecting a new dominant scatterer as a phase reference. Further, the performing step of the method includes storing and comparing the relative measures of focus provided by repeating of the steps to arrive at the corrected image which is the most focused and then saving the corrected image determined to be the the most focused. FOCAL PLANE ANTENNA ARRAY FOR MILLIMETER WAVES Patent
William M. Waters, inventor (to Navy) 17 Aug. 1993 10 p Filed 28 Apr. 92
(AD-D016034; US-Patent-5,237,334; US-Patent-Appl-SN-876696) Avail: US Patent and Trademark Office

A millimeter wave imaging system receives millimeter wave radiation and provides video imaging signals based thereon. The system comprises an imaging lens for receiving incoming radiation; a focal plane antenna array disposed at the focal plane of the lens on which radiation received by the lens is focused; and signal processing and display circuitry for processing the output of the antenna array and for producing and displaying corresponding video imaging signals. The focal plane antenna array comprises a planar array of a plurality of conical horns and circular waveguides which, in use, are disposed at the focal plane of the lens; and a microstrip detector assembly coupled to the waveguides for detecting the radiation received thereby. The microstrip detector assembly comprises a dielectric substrate having a plurality of microstrip conductors embedded therein, each microstrip conductor being coupled to a respective one of the waveguides, and a diode detector being connected to each microstrip conductor. (ITN-94-85229) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

When an optical beam propagates through a randomly inhomogeneous medium it acquires both phase and intensity fluctuations which are the result of random scattering and diffraction by the refractive index inhomogeneities in the random medium. While these fluctuations severely limit the performance of surveillance, communication and lidar systems that use the random medium as their transmission channel, the study of the statistical properties of the received fluctuation may also reveal useful information about the nature and structure of the random medium and the optical source (the inverse problem). In order to extract the information contained in the scattered field it is necessary to observe the scattered radiation field as completely as possible. In recent years, considerable effort has been dedicated, both theoretically and experimentally, to determine the intensity correlation function of two collinear initially overlapping optical beams, propagating in a random medium, and having different frequencies. Spectral diversity (simultaneous measurements of the received radiation at several different frequencies at the same point) not only adds important data to ease the solution of the inverse problem, but its incorporation into practical devices also significantly improves the signal to noise ratio in electro-optical systems. The experimental results can be explained in terms of in-system turbulence. Moreover, we have developed a novel optical method to measure the inner scale of turbulence from the bichromatic correlation coefficient by using this theoretical study. Author (ISA)

New methods are presented for the remote sensing, along a selected optical path, of atmospheric parameters such as the average wind speed and the turbulence-strength parameter. The theoretical basis of the method is presented. Turbulence-induced irregularities in the earth's atmospheric refractive index result from the existence of fluctuations in air temperature and velocity in eddies. Passage through such eddies causes distortion of optical wavefronts, leading to focusing or defocusing and local deviations in the direction of propagation and, through interference, irradiation fluctuations at a receiver. Although these random effects are complicated, statistical averaging enables the turbulence effects to be described quantitatively. Use of the wave equation for electromagnetic (EM) waves, with a random refractive index enables a formal integral solution to be found for the random EM field propagating through the turbulent medium. It is usual to use the statistical moments of this EM field to describe the spatial and temporal behavior of the intensity during the passage of the field through the atmosphere. The statistics of the turbulence structure and the nature of the interaction between the wave front and the turbulence eddies are embedded in these moments. The behavior is analyzed of a laser beam which propagates through a turbulent atmosphere and is reflected back to a receiver by a diffuse target on which a speckle type of field is being generated. The extended Huygens-Fresnel principle is used to obtain first- and second-order statistics of the received intensity of the reflected beam after propagation through weak turbulent media. ISA

CODED COMMUNICATIONS WITH NONIDEAL INTERLEAVING Ph.D. Thesis
Shaul Laufer Feb. 1991 185 p
(ITN-94-85235) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

Burst error channels - a type of block interference channels - feature increasing capacity but decreasing cutoff rate as the memory rate increases. Despite the large capacity, there is degradation in the performance of practical coding schemes when the memory length is excessive. A short-coding error parameter (SCEP) was introduced, which expresses a bound on the average decoding-error probability for codes shorter than the block interference length. The performance of a coded slow frequency-hopping communication channel is analyzed for worst-case partial band jamming and nonideal interleaving, by deriving expressions for the capacity and cutoff rate. The capacity and cutoff rate, respectively, are shown to approach and depart from those of a memoryless channel corresponding to the transmission of a single code letter per hop. For multiaccess communications over a slot-synchronized collision channel without feedback, the channel was considered as a block interference channel with memory length equal to the number of letters transmitted in each slot. The effects of an asymmetrical background noise and a reduced collision error rate were studied, as aspects of real communications. The performance of specific convolutional and Reed-Solomon codes was examined for slow frequency-hopping systems with nonideal interleaving. An upper bound is presented for the performance of a Viterbi decoder for a convolutional code with nonideal interleaving, and a soft decision diversity combining technique is introduced. This work deals with calculation of ray trajectories and P wave amplitudes in a three-dimensional medium characterized by variable velocity. The first chapter deals with the construction of a three-dimensional structure generator. A new method for creating complicated structures, such as those containing lenses or pinchouts is presented. The material interfaces are calculated by the pseudo polynomial spline interpolation method. The second chapter contains a review of the asymptotic ray theory. Simple algorithms for calculating the P wave trajectories in an inhomogeneous elastic medium, based on the solution of a system of six differential equations, are proposed. A method for calculating the directions of the reflected/transmitted rays is described. The third chapter deals with dynamic ray tracing. The propagating wave amplitudes are calculated by solving a system of 14 differential equations. This chapter also deals with the changes in amplitudes of the wave fronts upon crossing material dicontinuities. In the fourth chapter a scanning method for solving the two point ray tracing problem is presented. According to this method, a kinematic and dynamic ray tracing for common shot or normal incidence ray tracing is performed. At the end of the chapter, time-to-depth mappings are described by two methods: (A) ray tracing migration and (B) ray tracing inversion. Author (ISA)

A new speech recognition technique is proposed. This technique systematically describes acoustic characteristic variations using a large scale speech database, thereby, obtaining high recognition accuracy. Rules are extracted to represent knowledge concerning acoustic characteristic variations by observing the actual speech database. A general framework based on maps of the sets of variation factors to the acoustic feature spaces is proposed. A single recognition model is not used for each element of descriptive units regardless of the states of the variation factors. Large-scaled and systematic different recognition models are used for different states. A technique to structurize the representation of acoustic characteristic variations by clustering recognition models depending on variation factors is proposed. To investigate acoustic characteristic variations for phonetic contexts efficiently, word sets for reading texts of speech database are selected so that the maximum number of three phoneme sequences are covered in small number of words as possible. A selection algorithm, in which the first criterion is to maximize the number of different three phoneme sequences in the word set and the second criterion is to maximize the entropy of the three phonemes, is proposed. Read speed data of the word sets are collected and labelled as acoustic-phonetic segments. Experiments of speaker-independent word recognition using this speech database were conducted to show the description effectiveness of the acoustic characteristic variations using networks of acoustic-phonetic segments. The experiment shows the recognition errors are reduced. Basic framework for estimating the acoustic characteristics in unknown phonetic contexts using decision trees is proposed. Author (NASDA)

Phase-coded spread spectrum communication signals may be acquired and synchronized in the presence of interference with the aid of an adaptive array antenna under control of a least mean square algorithm performing power minimization. Although the signal to interference ratio at the adaptive array output port of such a system is adequate for acquisition and synchronization, it provides unacceptable message quality. Accordingly, an adaptive processor is provided which simultaneously performs beamforming and null steering to cancel interference affecting a desired signal. The null steering means cancels at least a portion of the undesired signal and is operative to reduce the gain of the radiation pattern of an array antenna in the direction of the source of the interference. The beamforming means enhances at least a portion of the desired signal and is operative to increase the gain of the radiation pattern of an array antenna in the direction of the source of the desired signal. Second means are provided for coordinating the null steering and beamforming means. The null steering and beamforming loops employ on and off epoch processors. Author (CISTI)

EQUALIZATION AND CANCELLATION OF NONLINEAR INTERSYMBOL INTERFERENCE IN A DISPERSIVE SATELLITE COMMUNICATION CHANNEL M.S. Thesis
Jeffrey Chan Aug. 1993 141 p
(ISBN-0-315-85147-3; CTN-94-61098) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Methods for compensating for nonlinear intersymbol interference (ISI) in satellite communication channels are examined, using a model of the satellite channel consisting of a dynamic linear filter followed by a static nonlinearity and then by another dynamic linear filter. Noise is added after the nonlinearity to represent the noise in the downlink to the ground receiver. Two general methods to compensate for the nonlinear ISI are equalization and cancellation. Six specific techniques for nonlinear ISI compensation were studied in detail. It is concluded that the best four techniques in terms of bit error probability are, in order from best to worst: fast orthogonal search equalization; fast orthogonal search cancellation; parallel cascades without the trailing extra linear filter, in a cancellation configuration; and parallel cascades with the trailing extra linear filter, in a cancellation configuration. Of these four, the last technique requires the least memory and processing time whereas the first requires the most memory and processing time. When these four methods are compared with the linear fractionally spaced equalizer, it is found that the bit error probability is greatest for the fractionally spaced equalizer, but the equalizer also requires the least memory and processing time. THE PERFORMANCE OF NONORTHOGONAL NONCOHERENT FREQUENCY HOPPED M-ARY FSK IN ADDITIVE WHITE GAUSSIAN NOISE, FADING AND JAMMING M.S. Thesis
Robert Allan Brett May 1993 235 p
(ISBN-0-315-85243-7; CTN-94-61102) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A tight upper bound approximation of the performance of noncoherent nonorthogonal M-ary frequency shift keying (MFSK) on fading channels is derived and verified by simulation. The performance of forward error correction coded nonorthogonal MFSK is compared to that of uncoded orthogonal MFSK occupying the same bandwidth and requiring the same energy per information bit. An analytical technique for finding the bit error probabilities of frequency hopped (FH) orthogonal MFSK in arbitrary combinations of jamming, fading, and noise is derived for an arbitrary number of signalling dimensions and an arbitrary level of diversity. No results previously existed for this problem. A versatile simulator is developed for computing the performance of FH nonorthogonal MFSK in the same environments. Comparisons are made between coded nonorthogonal FH/MFSK and uncoded orthogonal FH/MFSK in fading, additive white Gaussian noise, and multitone jamming. Author (CISTI)

The need for a systematic methodology for the analysis of aircraft electromagnetic compatibility (EMC) problems is examined. The available computer aids used in aircraft EMC analysis are assessed and a theoretical basis is established for the complex algorithms which identify and quantify electromagnetic interactions. An overview is presented of one particularly well established aircraft antenna to antenna EMC analysis code, the Aircraft Inter-Antenna Propagation with Graphics (AAPG) Version 07 software. The specific new algorithms created to compute cone geodesics and their associated path losses and to graph the physical coupling path are discussed. These algorithms are validated against basic principles. Loss computations apply the uniform geometrical theory of diffraction and are subsequently compared to measurement data. The increased modelling and analysis capabilities of the newly developed AAPG Version 09 are compared to those of Version 07. Several models of real aircraft, namely the Electronic Systems Trainer Challenger, are generated and provided as a basis for this preliminary comparative assessment. Issues such as software reliability, algorithm stability, and quality of hardcopy output are also discussed. Author (CISTI)

NON-ADAPTIVE ROBUST FILTERS FOR SPECKLE NOISE REDUCTION
Alejandro C. Frery and Sidnei J. S. SantAnna 1993 11 p
(INPE-5519-PRE/1794) Avail: CASI HC A03/MF A01

After briefly reviewing some classical filters for speckle removal, five filters with characteristics of robustness, suitable for speckle noise reduction, are derived and implemented. These filters are the ones based on the trimmed maximum likelihood and moments estimators, the ones based on the median, on the inter-quartile range, and on the median absolute deviation. Assuming that observations within a synthetic aperture radar image are outcomes of independent Rayleigh random variables, these filters exhibit a good performance from both the signal-to-noise reduction and from the edge preserving criteria. The problem of filtering in an image is posed as an estimation problem. Author

An SIS (Superconductor Insulator Superconductor) mixer is used for the astronomical millimeter radio observation because of its high sensitivity. The SIS mixer, however, must be cooled at the 4 K level, and either liquid helium or a GM (Gifford-McMahon) + JT refrigerator has been used for a long time. This paper describes the construction and experimental results of a compact SIS receiver, 720 mm in height, 260 mm in length, 260 mm in width, and 35 kg in weight. The technical point of the receiver was to adopt a 4 K GM refrigerator which used Er3Ni as a regenerator material to cool the SIS mixer. The cooling temperature of 3.4 K was achieved for the SIS mixer and the cool down time from the room temperature to the 4 K level was 4.5 hours. The power consumption for the compressor unit was 3.3 kW. This SIS receiver has been installed on the 45 meter antenna at Nobeyama Radio Observatory and used for astronomical observation for more than 3,000 hours. Author (NASDA)

(ISBN-0-315-84632-1; CTN-94-61081) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

An integrated multibeam satellite system with a new multiple access technique and an on-board baseband switch with priority rule is analyzed. The performance analysis includes the computation of the various packet loss, call blocking, and packet delays of a typical user in an integrated satellite internetworking environment. The uplink technique employed is a hybrid packet/circuit switched approach of the demand assignment type, while the downlink is a time division multiplexing technique. On board the satellite, a baseband nonblocking switch is used to route packets from input to output ports. Various amounts of input and output buffering as well as priority rules and a head-of-line blocking resolution algorithm are employed to improve the performance of the data services without affecting other services' performance. The delay and throughput characteristics of the services are determined by examining the relationships between the head-of-line resolution, buffer sizes, and internal speedup ratio of the baseband switch. AN EFFICIENT OFF-LINE ELECTRONIC CASH SYSTEM BASED ON THE REPRESENTATION PROBLEM
Stefan A. Brands Mar. 1993 80 p
(ISSN 0169-118X)
(CWI-CS-R9323; ETN-94-95436) Copyright Avail: CASI HC A05/MF A01

An offline electronic cash system based entirely on discrete logarithms is presented. Using the representation problem as a basic concept, some techniques are introduced that enable the construction of protocols for withdrawal and payment that do not use the cut and choose methodology of earlier systems. As a consequence, the cash system is much more efficient in both computation and communication complexity. The correctness of the system can be proven to a very great extent. The construction of an efficient cash system with security related to factoring or computation of RSA roots, in an analogous way to the discrete log based system, is discussed. The decision variant of the Diffie-Hellmann problem, that is strongly related to undeniable signatures, is discussed. ESA

FIBER OPTIC TRUE TIME-DELAY ARRAY ANTENNA FEED SYSTEM Patent Application
Ronald D. Esman, inventor (to Navy) and Lew Goldberg, inventor (to Navy) 17 Sep. 1993 39 p
(AD-D016063; US-Patent-Appl-SN-122671; Navy-Case-74788) Avail: CASI HC A03/MF A01

The fiber-optic true time-delay array antenna feed is a device for dynamically generating a plurality of identical electromagnetic radiation (EMR) signals with continuously variable time-delay separations. The EMR signal to be transmitted modulates a continuous-wave optical signal from a laser source which is applied to a plurality of high dispersion single-mode optical fibers acting as synchronized true time-delay modulators forming an array antennas feed system. Each fiber is chosen to have the same nominal time delay but a different net dispersion. Photodetectors convert the optical intensity back into an EMR electrical signal to feed each of the elements of the array antenna. DTIC

CALIBRATION OF SAR SYSTEMS Ph.D. Thesis - Stuttgart Univ. [KALIBRATION VON SAR-SYSTEMEN]
Manfred Zink May 1993 164 p In GERMAN
(ISSN 0939-2963)
(DLR-FB-93-18; ETN-94-95496) Avail: CASI HC A08/MF A02

A comprehensive description of necessary procedures for radiometric calibration of SAR (Synthetic Aperture Radar) systems is presented. Relative calibration allows successive measurements to be compared. Absolute calibration relates the SAR image intensity to radar backscattering coefficients and provides information about the accuracy of this relationship. Estimation and removal of all system related influences results in pure object signatures. The goal for the microwave remote sensing activities is to model the relationship between geophysical parameters, like soil moisture or leaf area index, and measured backscattering coefficients. Such quantitative analyses and the development and interpretation of models in different geophysical applications require calibrated data. With calibrated data the list of applications and geophysical parameters which can be monitored will extend considerably. ESA

SHORT-BLOCK DATA DETECTION TECHNIQUES EMPLOYING CHANNEL ESTIMATION FOR FADING TIME-DISPERSIVE CHANNELS Ph.D. Thesis
Stewart N. Crozier 26 Mar. 1990 236 p
(ISBN-0-315-58970-1; CTN-94-60997) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Three short-block data detection techniques based on linear, nonlinear decision directed, and maximum likelihood estimation principles are investigated, using short alternating blocks of data and training symbols. The training blocks are useful for both channel tracking and data block detection; each data block is detected as a unit. Previous restrictions imposed on short-block detection schemes were removed, resulting in reduced complexity algorithms (useful at higher signaling rates) and higher throughput efficiency. The higher the signaling rate, the more inherent diversity a time-dispersive fading channel can provide, and the better the error rate performance. Performance is evaluated for phase shift keying using a Rayleigh fading channel model with severe time dispersion. The performance is compared to that of conventional linear and decision feedback equalizers. The block detection schemes examined all require an estimate of the channel impulse response. A channel estimation algorithm is presented and optimum training sequences are determined and tabulated. A simple formula for the expected degradation in performance caused by channel estimation errors is also derived. Simulation results confirm the accuracy of this approximation for high signal to noise ratios. Author (CISTI)

The pulse receiving characteristics of several thin-wire antennas were investigated. A loop antenna with uniformly distributed impedance was analyzed using an equivalent circuit, and the frequency- and time-domain receiving characteristics of a resistively loaded loop antenna were obtained. The antenna was found to be dispersive and not suitable for receiving electromagnetic pulses or transients. Resistively loaded straight dipole antennas were then considered. The Wu-King resistively loaded dipole was found to have the maximally flat frequency response close to the upper roll-off frequency, when terminated with a high impedance load. Thirdly, a time-domain stepping in time procedure was developed for analyzing V-antennas. After identifying limitations of these antennas in receiving fast pulses and transient, a new V-antenna consisting of a resistively loaded thin-wire V-dipole or monopole was developed. This antenna has 3 dB bandwidth from 110 MHz to 10 GHz and higher sensitivity than the Wu-King antenna. An experimental V-antenna and Wu-King monopole antenna were fabricated using thin film deposition and tested. The V-antenna is capable of receiving a 520-ps near-Gaussian pulse without significant distortion and has a flat receiving response from 35 MHz to 3 GHz. The Wu-King antenna had an upper roll-off frequency of about 300 MHz. Author (CISTI)

This report presents results of a series of site and noise surveys performed in Alaska. Surveys were performed at the former OTH-B site at Gulkana with the aim of determining the spectrum occupancy and background noise level at nominally 38 MHz, 420 MHz, and 440 MHz. Three site surveys were performed at Elmendorf AFB near Anchorage, aimed at determining the spectrum occupancy and background noise levels at 40 to 50 MHz. Noise surveys were also performed at three existing radar sites, Galena, Kotzebue, and Cape Lisburne, at 40 to 50 MHz. This report contains a presentation of the survey and measurement methodology, including antenna patterns, absolute noise level calibrations, and noise level predictions. The features of the individual sites are presented with a discussion of the data collected. Author

POLARIZABILITY MATRIX OF LAYERED CHIRAL SPHERE

M. E. Ermutlu and A. H. Sihvola Jun. 1993 15 p Sponsored by Suomen Akatemja Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB94-132834; ISBN-951-22-1667-1) Avail: CASI HC A03

Using quasi-static analysis, this article solves the dipole moments that are induced by electromagnetic field in a layered chiral sphere, consisting of a spherical core and a spherical shell. The result is the low-frequency polarizability of the sphere, and can be used to calculate the Rayleigh scattering of this object. Due to the chirality, the polarizability matrix has four components, electric and magnetic co- and cross-polarizabilities, that are functions of the permittivity, permeability, and chirality parameters of the core and shell materials and the ratio of their radii. The analysis is based on straightforward expansions of the field solutions in each region, and on making use of the boundary conditions, which leads to the inversion of a 8 x 8 matrix. The result can be shown to satisfy all the checks of earlier known special cases of homogeneous chiral sphere and layered dielectric-magnetic sphere. NTIS

FIELDS AND POTENTIALS IN GENERAL UNIAXIAL BIANISOTROPIC MEDIA I. AXIAL SOURCES Report No. 147

Werner S. Weiglhofer (Glasgow Univ., Scotland.) and Ismo V. Lindell May 1993 16 p

(ISSN 0784-848X)

(PB94-132875; ISBN-951-22-1582-9) Avail: CASI HC A03/MF A01

An electromagnetic field representation in terms of two scalar Hertz potentials is derived pertaining to source-free regions and fields radiated from axial sources in general uniaxial bianisotropic media. The corresponding scalar Green's functions are obtained as single integral representations. Provided that the eight medium parameters of the uniaxial bianisotropic medium fulfill one algebraic relation, complete analytic solutions become available. Because of the general nature of the medium, the theoretical formalism is applicable to a wide variety of materials and substances which--through impressive advances in the materials and macromolecular sciences--are playing an ever more important role in the fabrication of optical and electronic devices. PLANE WAVE PROPAGATION AND POLARIZATION PROPERTIES IN TRANSVERSELY BIANISOTROPIC UNIAXIAL MEDIUM Report No. 146

Paivi K. Koivisto May 1993 18 p See also PB93-187219

(ISSN 0784-848X)

(PB94-132883; ISBN-951-22-1581-0) Avail: CASI HC A03/MF A01

A transversely bianisotropic uniaxial medium can be constructed by mixing metal helices into an isotropic host medium in such a way that the axes of the helices are perpendicular to a fixed direction in space but randomly oriented in the transverse plane. In general, the host medium can be either reciprocal or nonreciprocal. Eigenwaves, expressions for the plane wave fields, and polarization behavior are derived for the plane wave propagating perpendicular to the symmetry axis. The polarization properties of chiral and reciprocal transversely bianisotropic uniaxial media are studied in order to find a suitable parameter combination for a polarization transformer. Several numerical examples are given to illustrate the propagation properties of the transversely bianisotropic uniaxial medium. NTIS

EIGENWAVES IN THE GENERAL UNIAXIAL BIANISOTROPIC MEDIUM WITH SYMMETRIC PARAMETER DYADICS Report No. 148

Ismo V. Lindell and Ari J. Viitanen May 1993 19 p

(ISSN 0784-848X)

(PB94-132891; ISBN-951-22-1583-7) Avail: CASI HC A03/MF A01

The uniaxial bianisotropic medium is a generalization of the well-studied bi-isotropic and chiral media. Special cases of uniaxial media with axial or transverse chirality were previously studied by these authors, and they were seen to have interesting and practical polarization transformation properties and, moreover, to be more easily fabricable than truly isotropic (bi-isotropic) chiral media. The present problem considers plane-wave propagation in the most general uniaxial bianisotropic medium, with symmetric parameter dyadics. The dispersion equation for such a dyadic is solved together with the eigenpolarizations of the two eigenwaves. Numerical examples for the wavenumbers corresponding to the two eigenwaves of the medium are given. Applications as a polarization transformer are discussed. NTIS

ELECTROMAGNETIC MODELING OF BI-ISOTROPIC MEDIA

A. Sihvola May 1993 41 p

(PB94-132909; ISBN-951-22-1584-5) Avail: CASI HC A03/MF A01

The topic of this article is the characterization of heterogeneous bi-isotropic media. The chiral and nonreciprocal materials are treated as special cases. First the polarizability matrices are presented for spherical and ellipsoidal bi-isotropic inclusions. With these, the mixing problem is attacked, where the full effective bi-isotropic material parameters are calculated for a mixture containing bi-isotropic inclusions. Special emphasis is on the physical interpretation of the results, i.e., the ways to see and understand the manner in which the individual nonreciprocity and chirality parameters affect the macroscopic properties of the medium. The focus is also on the duality and symmetry properties of the magnetoelectric parameter expressions. Also, time dispersion is studied; the effect of the mixing process on the dispersion in the chirality of the mixture is analyzed. Finally, it is shown that there exist deep analogies between the polarizabilities of bi-isotropic media on one hand and those of anisotropic media on the other. NTIS

ELECTROSTATIC IMAGE SOLUTION FOR THE CONDUCTING PROLATE SPHEROID

J. C. E. Sten and I. V. Lindell Mar. 1993 16 p See also PB92-142199

(PB94-133154; ISBN-951-22-1648-5) Avail: CASI HC A03/MF A01

Electrostatic image theory for a point charge on the axis of a perfectly conducting prolate spheroid is formulated. The exact image expression is found using the Havelock identity, according to which the external harmonics of the potential solution emanate from a system of continuous image sources distributed along the focal line. Many tests for the theory are performed and graphical examples given. In the case of a slightly prolate sphere, the first correction to the image solution for the conducting sphere by Lord Kelvin is developed. An expression for the image polarization density function is derived for the dipolar source. NTIS

ANALYTIC SOLUTION FOR THE DYADIC GREEN'S FUNCTION OF A NONRECIPROCAL UNIAXIAL BIANISOTROPIC MEDIUM
W. S. Weiglhofer and I. V. Lindell Jun. 1993 11 p
(PB94-133162; ISBN-951-22-1642-6) Avail: CASI HC A03/MF A01

The dyadic Green's function for an unbounded nonreciprocal uniaxial bianisotropic medium is derived in explicit form. Such uniaxial bianisotropic media can be realized by randomly dispersing uniaxial metallic inclusions with parallel orientations into an isotropic host medium. The availability of an analytic solution for the dyadic Green's function marks therefore an important step towards an understanding of radiation from sources and propagation of waves in composite materials. IMAGE THEORY FOR DC PROBLEMS INVOLVING A CONDUCTING HALF SPACE BOUNDED BY THE GENERAL ANISOTROPIC IMPEDANCE SURFACE
I. V. Lindell and M. J. Flykt May 1993 19 p See also PB93-224996
(PB94-132917; ISBN-951-22-1592-6) Avail: CASI HC A03/MF A01

A novel image theory is introduced. The theory is applicable to DC problems involving current sources in an isotropic conducting half space bounded by a planar, reciprocal, anisotropic impedance surface. The theory is a generalization involving an isotropic impedance surface and that involving a perfect anisotropic impedance surface with zero and infinite resistivities in two orthogonal directions on the plane. The image for a point current source is a combination of an electric line current source and a transverse quadrupole magnetic line current source. The magnetic current component vanishes for vanishing anisotropy while the electric current component vanishes for perfect anisotropy. NTIS

GREEN DYADIC AND DIPOLE FIELDS FOR A MEDIUM WITH ANISOTROPIC CHIRALITY
I. V. Lindell and W. S. Weighlhofer Jun. 1993 15 p See also PB93-224764
(PB94-132933; ISBN-951-22-1637-X) Avail: CASI HC A03/MF A01

A closed-form expression is derived for the Green dyadic corresponding to a reciprocal bianisotropic medium with isotropic permittivity and permeability and arbitrary anisotropic chirality. Such a medium can be approximated, for example, by inserting in an isotropic host medium an equal number of similar right- and left-handed metal helices with suitable orientations. The solution is applied to determine the electric field of an electric dipole embedded in such a medium. Evaluation of its far-field shows that the wave is split into two plane waves with different wave-normal directions. NTIS

DIELECTRIC POLARIZABILITY OF SPHERE WITH ARBITRARY ANISOTROPY
A. H. Sihvola Jun. 1993 12 p
(PB94-133113; ISBN-951-22-1668-X) Avail: CASI HC A03/MF A01

The polarizability of a dielectrically anisotropic sphere is studied. The anisotropy is general, consisting of a symmetric and antisymmetric part of the permittivity dyadic. The polarizability is also dyadic with its components depending on the relations of the permittivity components of the material. In certain special cases, the components of the polarizability matrix decouple and become only functions of the corresponding permittivity components, but in general, all nine polarizabilities depend on all nine permittivities. (VTT-PUBS-132; ISBN-951-38-4250-9; ETN-94-95239) Copyright Avail: CASI HC A03/MF A01

The thermal design of electronics in the space environment is investigated. The effects of environmental and design parameters on the thermal behavior of printed circuit boards are discussed. The tools that can be used to achieve more solid designs, to increase reliability, and decrease failure rate of printed circuit boards are presented. A thermal design procedure for spaceborne electronics and guidelines to follow in designing electronics to be operated in space are given. The procedure is a three step iterative cycle where first, circuit board blueprints are scanned with digital scanner to determine the copper density distribution for the board. The second phase is to determine the thermal resistance for radiative process for preset node size in a given temperature range using a program made for this purpose. These values are used to make a model of the board. ESA

ELECTRIC-FIELD DEPENDENCE OF ELECTROREFLECTANCE AND PHOTOCURRENT SPECTRA AT VISIBLE WAVELENGTHS IN MOVPE-GROWN InAlGaP MULTIPLE STRAINED QUANTUM-WELL STRUCTURES
I. J. Fritz, O. Blum, R. P. Schneider, Jr., A. J. Howard, and D. M. Follstaedt 1993 6 p Presented at the Fall Meeting of the Materials Research Society, Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC04-94AL-85000)
(DE94-004692; SAND-93-1529C; CONF-931108-20) Avail: CASI HC A02/MF A01

The authors present electric-field dependent electroreflectance and photocurrent spectra of visible-bandgap In(x)(Al(y)Ga(1 - y))(sub 1 - x)P/In(x')(Al(y'))Ga(1 - y')(sub 1 - x')P multiple-quantum-well (MQW) structures. These structures, grown by metal-organic vapor phase epitaxy on 6 deg-misoriented (100) GaAs substrates, have undoped MQW's sandwiched between doped In(0.5)Al(0.5)P layers, forming p-i-n diodes. Quantum-well compositions in the range 0.46 less than or equal to x less than or equal to 0.52 and 0 less than or equal to y less than or equal to 0.4, corresponding to bandgaps in the red to yellow-green range, were used. The Stark shifts in these various samples were measured and found to depend on the details of the Mg p-type doping profile, confirming important diffusion effects, in agreement with secondary ion mass spectrometry and capacitance-voltage data. The results show that these new materials are promising for visible-wavelength optical modulator applications. DOE

FILTERING, CODING, AND COMPRESSION WITH MALVAR WAVELETS M.S. Thesis
Stephen R. Hall Dec. 1993 156 p
(AD-A274055; AFIT/GSO/Eng/93D-02) Avail: CASI HC A08/MF A02

This thesis develops and evaluates a number of new concepts and tools for the analysis of signals using Malvar wavelets (lapped orthogonal transforms). Windowing, often employed as a spectral estimation technique, can result in irreparable distortions in the transformed signal. By utilizing the Malvar wavelet, any signal distortion resulting from the transformation can be eliminated or cancelled during reconstruction. This is accomplished by placing conditions on the window and the basis function and then incorporating the window into the orthonormal representation. Paradigms for both a complex-valued and a real-valued Malvar wavelet are summarized. I-lie algorithms for the wavelets were implemented in the DOD standard language, Ada. The code was verified to ensure perfect reconstruction could be obtained, and experiments were performed using the wavelet programs. Various compression techniques were investigated and evaluated using the Malvar wavelet in both homomorphic and non-homomorphic systems. The Malvar wavelet has the unique ability to overlap adjacent windows without increasing the number of transform coefficients. Various amounts of window overlap were investigated to determine if there is an optimal amount which should be used. In addition, the real-valued basis function was used to attempt real-valued deconvolution. DTIC

REFERENCE ELECTRODES FOR SOLID POLYMER ELECTROLYTES
C. S. Johnson and D. W. Dees 1993 13 p Presented at the 184th Meeting of the Electrochemical Society, New Orleans, LA, 10-15 Oct. 1993
(Contract W-31-109-eng-38)
(DE94-004583; ANL/CMT/CP-79723; CONF-931024-1) Avail: CASI HC A03/MF A01

Electrochemical experiments were conducted on a binary metallic lithium-tin alloy that may be suitable as a reference electrode of the first kind in studies of lithium-polymer batteries. Two types of tin electrodes were tested: bulk tin foil and tin thin films deposited on a stainless steel substrate. Electrochemical test cells were fabricated, with tin, metallic lithium, poly(ethylene oxide), and lithium trifluoromethanesulfonate as electrodes and polymer electrolyte material. To form the alloy, the tin electrodes were galvanostatically loaded in situ with lithium. Each cell reached one or more steady-state voltage plateaus during the electrochemical reduction of lithium cations at the tin electrode surface. The lithiated tin foil electrode (1 C/cm(exp 2) of charge passed; area approximately 5 cm(exp 2); thickness = 1.0 mm) demonstrated good voltage stability over months under open-circuit conditions. This electrode maintained an average open circuit voltage of 0.7336 V with only +/- 0.17 mV variance. Composition of phases in the thin film electrodes (x in Li(x)Sn) was coulometrically varied via reversible lithium loading and unloading reactions. Results show that three different, two-phase compositions may be formed that maintain flat voltage regions at approximately 0.53, 0.63, and 0.73 V vs lithium metal. DOE

ADVANCED QUALIFICATION TECHNIQUES
P. S. Winokur, M. R. Shaneyfelt, T. L. Meisenheimer, and D. M. Fleetwood 1993 11 p Presented at the 2nd European Conference on Radiations and Their Effects on Devices and Systems, Saint Malo, France, 13-16 Sep. 1993
(Contract DE-AC04-94AL-85000)
(DE94-003709; SAND-93-1323C; CONF-930953-2) Avail: CASI HC A03/MF A01

This paper demonstrates use of the Qualified Manufacturers List (QML) methodology to qualify commercial and military microelectronics for use in space applications. QML 'builds in' the hardness of product through statistical process control (SPC) of technology parameters relevant to the radiation response, test structure to integrated circuit (IC) correlations, and techniques for extrapolating laboratory test results to low-dose-rate space scenarios. Each of these elements is demonstrated and shown to be a cost-effective alternative to expensive end-of-line IC testing. Several examples of test structured-IC correlations are provided and recent work on complications arising from transistor scaling and geometry is discussed. The use of a 10-keV x-ray wafer-level test system to support SPC and establish 'process capability' is illustrated and a comparison of 10-keV x-ray and Co-60 gamma irradiations is provided for a wide range of CMOS technologies. The x-ray tester is shown to be cost-effective and its use in lot acceptance/qualification is recommended. Finally, a comparison is provided between MIL-STD-883D, Test Method 1019.4, which governs the testing of packaged semiconductor microcircuits in the DoD, and ESA/SSC Basic Specification No. 22900, Europe's Total Dose Steady-State Irradiation Test Method. Test Method 1019.4 focuses on conservative estimates of MOS hardness for space and tactical applications, while Basic Specification 22900 focuses on improved simulation of low-dose-rate space environments. OBJECT IMAGING ACCOMPLISHED WITH AN INTEGRATED CIRCUIT ROBOTIC TACTILE SENSOR INCORPORATING A PIEZOELECTRIC POLYVINYLIDENE FLUORIDE THIN FILM M.S. Thesis
John M. Emmert Dec. 1993 259 p
(AD-A274038; AFIT/GE/Eng/93D-06) Avail: CASI HC A12/MF A03

The purpose of this research effort was to investigate the performance of a piezoelectric tactile sensor design and appropriately refine it. The sensor was fabricated from an 8 x 8 electrode array MOS integrated circuit. Each taxel in the array was 400 microns x 400 microns. A 6 mm x 6 mm piece of piezoelectric polyvinylidene fluoride was adhered to the electrode array using a urethane dielectric adhesive to form the active sensing area of the sensor. An amplifier was investigated to enhance the range of the tactile sensor's output signal. The amplifier is a high input impedance differential amplifier with a linear range from 1 to 17 V. The unique feature of the differential amplifier was that it used a power supply of only 12 V. The spatial resolution of the sensor is 0.7 mm. The lower force limit of the sensor is 1 g while the upper limit, limited by a previous amplifier design with a range from 2.5 to 7 V, is 130 g. The dynamic range of the sensor is 130:1. The sensor's force sensitivity is 7.35 g. The pyroelectric bandwidth of the sensor is 0.083 Hz, and the temperature sensitivity of the sensor is 0.39 C. DTIC

Systems, Deerfield Beach, FL, 6-8 Dec. 1993
(Contract DE-AC04-94AL-85000)
(DE94-002651; SAND-93-2681C; CONF-931204-1) Avail: CASI HC A02/MF A01

We have evaluated a wide variety of microcellular carbon foams prepared by the controlled pyrolysis and carbonization of several polymers including: polyacrylonitrile (PAN), polymethacrylonitrile (PMAN), resorcinol/formaldehyde (RF), divinylbenzene/methacrylonitrile (DVB), phenolics (furfuryl/alcohol), and cellulose polymers such as Rayon. The porosity may be established by several processes including: gelation (1-5), phase separation (1-3,5-8), emulsion (1,9,10), aerogel/xerogel formation (1,11,12,13), replication (14), and activation. In this report we present the complex impedance analysis and double layer charging characteristics of electrodes prepared from one of these materials for double layer capacitor applications, namely activated cellulose derived microcellular carbon foam. DOE

A PHYSICS-BASED HETEROJUNCTION BIPOLAR TRANSISTOR MODEL FOR INTEGRATED CIRCUIT SIMULATION M.S. Thesis
James A. Fellows Dec. 1993 250 p
(AD-A274081; AFIT/GE/Eng/93D-07) Avail: CASI HC A11/MF A03

The purpose of this research effort was to derive a physics-based dc model for a Heterojunction Bipolar Transistor (HBT). The dc model was then linearized to arrive at a small-signal model that accurately predicts the device's electrical behavior at microwave frequencies. This new model offers features not found in previous analytical or physics-based HBT models such as consideration of a cylindrical emitter-base geometry and is direct implementation into SPICE (Simulation Program with Integrated Circuit Emphasis). The device model parameters were determined from a knowledge of the device material, geometry, and fabrication process. The model was then developed by using semiconductor physics to calculate modified parameters for the existing SPICE bipolar junction transistor (BJT) model. DTIC

EXPLORATORY TECHNOLOGY RESEARCH PROGRAM FOR ELECTROCHEMICAL ENERGY STORAGE
K. Kinoshita, ed. Oct. 1993 34 p
(Contract DE-AC03-76SF-00098)
(DE94-003479; LBL-34081) Avail: CASI HC A03/MF A01

This report summarizes the progress made by the Exploratory Technology Research (ETR) Program for Electrochemical Energy Storage during calendar year 1992. The primary objective of the ETR Program, which is sponsored by the US Department of Energy (DOE) and managed by Lawrence Berkeley Laboratory (LBL), is to identify electrochemical technologies that can satisfy stringent performance, durability, and economic requirements for electric vehicles (EV's). The ultimate goal is to transfer the most-promising electrochemical technologies to the private sector or to another DOE program (e.g., SNL's Electric Vehicle Advanced Battery Systems Development Program, EVABS) for further development and scale-up. Besides LBL, which has overall responsibility for the ETR Program, LANL and BNL have participated in the ETR Program by providing key research support in several of the program elements. The ETR Program consists of three major elements: Exploratory Research; Applied Science Research; and Air Systems Research. The objectives and the specific battery and electrochemical systems addressed by each program element are discussed in the following sections, which also include technical summaries that relate to the individual programs. Financial information that relates to the various programs and a description of the management activities for the ETR Program are described in the Executive Summary. DOE

METHOD OF OPTIMIZING THE CHARGING OF A BATTERY OF STORAGE CELLS, AND APPARATUS FOR PERFORMING THE METHOD Patent
Guy Busson, inventor (to Navy) 12 Oct. 1993 10 p Filed 7 Feb. 1992
(AD-D016066; US-Patent-5,252,906; US-Patent-Appl-SN-832586) Avail: CASI HC A02/MF A01

The invention relates to a method enabling a battery of storage cells to be charged in a charging mode for compensating for discharging to an external circuit, or in a maintenance mode for compensating for self-discharging of the battery. The method consists in: determine the charging capacity of the battery, as a function of the temperature (Tb) of the battery, the charging capacity decreasing and becoming less than the reference capacity when the temperature increases during a charging period; calculating the electricity balance between the quantity of electricity received by the battery and the quantity of electricity supplied by the battery to an external circuit; and deciding to switch from maintenance mode to charging mode each time that the electricity balance is less than the charging capacity. Author (DTIC)

A SHUTTLE MECHANISM FOR MOLTEN-ELECTROLYTE LITHIUM BATTERIES
T. D. Kaun and P. A. Nelson 1993 12 p Presented at the 184th Meeting of the Electrochemical Society, New Orleans, LA, 10-15 Oct. 1993
(Contract W-31-109-eng-38)
(DE94-002914; ANL/CMT/CP-79729; CONF-931024-5) Avail: CASI HC A03/MF A01

The lithium-transport rates arising from a lithium shuttle mechanism (LSM) were examined by potentiometric control of a lithium-alloy electrode in a temperature range of 400 to 515 C in three electrolytes: LiCl-KCl, LiCl-LiBr-KBr, and LiF-LiCl-LiBr. Lithium transport in Li/FeS(x) cells by LSM was found to occur by diffusion of reduced lithium species across the separator layer, which was controlled by the Li-activity of the Li-alloy electrode. Solubility of lithium was strongly affected by electrolyte composition, especially K(+) content, which in turn regulated the lithium transport rate. As evidenced by LSM rates, the solubilized lithium would appear to form dimers (e.g. Li2(+) or LiK(+)). The half-cell self-discharge rates, which were measured, correlate well with self-discharge rates in developmental cells ranging from 0.1 to 10 mA/sq cm. Innovative application of the LSM has led to the development of overcharge tolerant Li/FeS(x) cells. A bimodal self-discharge characteristic (a 20-fold increase toward the end of charge) results from a 150-250 mV step increase in lithium activity of a two-phase Li-alloy electrode (Li-Al plus Li-Al 5Fe2). Three versions of the battery cell (100 sq cm separator area) have been demonstrated: LiAl+Li5Al5Fe2 (10% of capacity) /LiCl-LiBr-KBr(MgO)/FeS2, as well as a FeS-type, (both operated at 400 C) and LiAl+Li5Al5Fe2 (10% of capacity) /LiF-LiCl-LiBr(MgO)/FeS (operated at 475C). These cells exhibit a unique combination of overcharge capacity and extended trickle-charge tolerance at 2-5 mA/sq cm. Additionally, Li/FeS2 cells having overcharge tolerance have operated with stable performance for greater than 500 cycles. The overcharge tolerance rates are sufficient for battery cells to exhibit built-in charge/equalization capability by way of full-battery trickle charging. DOE

TEST METHODS AND CUSTOM HARDWARE FOR FUNCTIONAL TESTING OF A HIGH SPEED GaAs DRAM M.S. Thesis
Michael P. Butler Sep. 1993 78 p
(AD-A274859) Avail: CASI HC A05/MF A01

The goal of this project is to produce a digital circuit operating near a frequency of 250 MHz to test a new experimental gallium arsenide (GaAs) dynamic random access memory (DRAM). This thesis presents the design of the digital circuit using 'off-the-shelf' emitter coupled logic (ECL) and the design of a six layer printed circuit test fixture. The use of ECL is illustrated including general design rules, high speed design considerations, and basic transmission line theory. Finally, the design is laid out and simulated using commercially available computer aided design (CAD) and computer aided manufacturing (CAM) tools. Examples and shortcomings of schematic capture, logic simulation, PCB design, and auto-routing are discussed as applicable to fabrication of the final product. DTIC

HYBRID POWER SYSTEM FOR REMOTE COMMUNICATIONS STATIONS M.S. Thesis
Christopher R. Pietras Sep. 1993 186 p
(AD-A274963) Avail: CASI HC A09/MF A02

The U.S. Coast Guard is upgrading communications equipment at remote sites in Alaska in support of the Coastal Voice Distress Network. The VHF-FM Search and Rescue sites are powered by a primary power system consisting of a thermoelectric generator. Thermoelectric generators are very inefficient devices which consume vast quantities of propane to create electricity. The upgrade necessitates added power requirements on the power supply system at the remote sites. These requirements compel the redesign and/or upgrade of the power system. If thermoelectric generators continue to be utilized as the primary power system, additional helicopter visits to the sites to deliver propane will be required. These helicopter flights are costly and sometimes hazardous due to severe weather. This thesis investigates a variety of power system options capable of providing electrical power to the communications sites. Specifically, this thesis addresses three objectives. The first is a discussion of current alternative energy source technology available to supply the required power. The second is an analysis of the specific power system requirements and constraints. The third objective and major thrust of the research is the design of a reliable hybrid power system for this application, capable of utilizing the inexhaustible natural energy available at the remote sites. The engineering parameters for a hybrid power system were studied and calculations made based on commercially available components. The difficulties in the design due to extreme weather conditions and unavailability of natural power resource information at specific sites are addressed. This thesis presents the groundwork associated with hybrid power system designs for use at remote communications sites. DTIC

MICROWAVE AND PULSED POWER
E. K. Freytag Mar. 1993 30 p
(Contract W-7405-eng-48)
(DE94-003019; UCRL-ID-112776) Avail: CASI HC A03/MF A01

The goals of the Microwave and Pulsed Power thrust area are to identify realizable research and development efforts and to conduct high-quality research in those pulse power and microwave technologies that support existing and emerging programmatic requirements at Lawrence Livermore National Laboratory (LLNL). Our main objective is to work on nationally important problems while enhancing our basic understanding of enabling technologies such as component design and testing, compact systems packaging, exploratory physics experiments, and advanced systems integration and performance. During FY-92, we concentrated our research efforts on the six project areas described in this report. We are investigating the superior electronic and thermal properties of diamond that may make it an ideal material for a high-power, solid-state switch. We are studying the feasibility of using advanced Ground Penetrating Imaging Radar technology for reliable non-destructive evaluation of bridges and other high-value concrete structures. These studies include conceptual designs, modeling, experimental verifications, and image reconstruction of simulated radar data. We are exploring the efficiency of pulsed plasma processing techniques used for the removal of NO(x) from various effluent sources. We have finished the investigation of the properties of a magnetically delayed low-pressure gas switch, which was designed here at LLNL. We are applying statistical electromagnetic theory techniques to help assess microwave effects on electronic subsystems, by using a mode stirred chamber as our measurement tool. We are investigating the generation of perfluoroisobutylene (PFIB) in proposed CFC replacement fluids when they are subjected to high electrical stresses and breakdown environments. DOE

IN SITU SPECTROSCOPIC APPLICATIONS TO THE STUDY OF RECHARGEABLE LITHIUM BATTERIES Final Report
Rachael Barbour, Sunghyun Kim, Donald Tryk, and Daniel A. Scherson Aug. 1993 20 p Prepared in cooperation with California Univ., Berkeley. Lawrence Berkeley Lab.
(Contract DE-AC03-76SF-00098)
(DE94-003478; LBL-34514) Avail: CASI HC A03/MF A01

In situ attenuated total reflection Fourier transform infrared spectroscopy (ATR/FTIR) has been employed to examine the reactivity of lithium towards polyethylene oxide (PEO) at ca. 60 C. Uncertainties regarding the cleanliness of the Li surfaces were minimized by electrodepositing a film of metallic Li directly onto a thin layer of gold (ca. 60 Angstrom) vapor deposited on a Ge ATR optical element during the spectroscopic measurements. The ATR/FTIR features observed upon stripping the Li layer were consistent with the formation of alkoxide-type moieties resulting from the Li-induced cleavage of the ether-type functionalities. Electronic and structural aspects of the electrochemical insertion of lithium from nonaqueous electrolytes into FeS2 have been investigated using in situ Fe K-edge x ray absorption fine structure (XAFS). The results obtained indicate that the incorporation of Li(sup +) in the pyrite lattice brings about a marked decrease in the amplitude of the extended XAFS (EXAFS) oscillations, particularly for shells associated with distant atoms and a rounding of the x ray absorption near edge structure (XANES) region. An analysis of the EXAFS spectra yielded a value for the FeS distance of 2.29 +/- 0.02 Angstrom. On this basis and additional in situ room temperature Fe-57 Mossbauer effect spectroscopy data for the same system, it has been proposed that the electrically formed material involves a highly disordered, possibly amorphous, form of Fe(1-x)S, with Li+ counterbalancing the charge. DOE

MULTICHIP MODULE HIGH SPEED TESTING Quarterly Progress Report, 1 Oct. - 31 Dec. 1993
Robert J. Davis and David H. Auston 31 Dec. 1993 4 p
(Contract N00014-91-J-4045)
(AD-A274873) Avail: CASI HC A01/MF A01

Last quarter, we reported Al/SiO2/Al capacitor structures formed on an optical fiber, as the first step toward an electrooptic test probe. We have now fabricated an amorphous hydrogenated silicon (a-Si:H) photodetector directly on an optical fiber. We have been investigating the use of electrooptically active polymers for the purpose of electrooptic testing. Important problems remaining to be solved are low electrooptic efficiency and geometry; detection system speed, efficiency, and noise; and optical alignment. DTIC

OPTOELECTRONIC TECHNOLOGY CONSORTIUM Quarterly Technical Report No. 6, 1 Oct. - 31 Dec. 1993
Mary Hibbs-Brenner 4 Jan. 1994 10 p
(Contract MDA972-92-C-0071; ARPA Order 8351C)
(AD-A274909) Avail: CASI HC A02/MF A01

The Optoelectronic Technology Consortium has been established to position U.S. industry as the world leader in optical interconnect technology by developing, fabricating, integrating and demonstrating the producibility of optoelectronic components for high-density/high-data-rate processors and accelerating the insertion of this technology into military and commercial applications. This objective will be accomplished by a program focused in three areas. OETC will demonstrate an aggregate data transfer rate of 16 Gb/s between single transmitter and receiver packages, as well as the expandability of this technology by combining four links in parallel to achieve a 64 Gb/s link. By collaborating during the precompetitive technology development stage, OETC will advance the development of optical components and produce links for a multiboard processor testbed demonstration. Under the OETC program Honeywell will develop packaged AlGaAs arrays of waveguide modulators and polymer based, high density, parallel optical backplane technology compatible with low-cost manufacturability. CHARACTERISTICS AND DEVELOPMENT REPORT FOR THE T1576 POWER SUPPLY AND THE MC3935 BATTERY
P. C. Butler and C. E. Robinson Oct. 1993 95 p
(Contract DE-AC04-94AL-85000)
(DE94-003675; SAND-91-2845) Avail: CASI HC A05/MF A01

This report describes the requirements, designs, performance, and development histories for the T1576 power supply and the MC3935 rechargeable battery. These devices are used to power Permissive Action Link (PAL) ground controllers. The T1576 consists of a stainless steel container, one SA3553 connector, and one MC3935 battery. The MC3935 is a vented nickel/cadmium battery with 24 cells connected in series. It was designed to deliver 5.5 Amp-hours at 25 C and the one-hour rate, with a nominal voltage of 28 V. The battery was designed to operate for 5 years or 500 full charge/discharge cycles. The power supply is expected to last indefinitely with replacement batteries and hardware. DOE

LOW THRESHOLD ALL-OPTICAL CROSSBAR SWITCH ON GaAs-GaAlAs CHANNEL WAVEGUIDE ARRAYS Annual Report, 14 Aug. 1992 - 14 Aug. 1993
Tomasz Jannson 14 Aug. 1993 31 p
(Contract F49620-92-C-0047)
(AD-A274971; AFOSR-94-0033TR) Avail: CASI HC A03/MF A01

POC proposed a 10 x 10 all-optical crossbar switch based on an optically activated modulator. A laser beam with an energy higher than the bandgap of the GaAs switches the propagation direction of the guided beam. Strong index modulation (greater than 2%) can be induced by this method, which is not dependent on polarization for the EO effect. Both TE and TM guided waves have the same induced index change. Because there are no electrical contacts, this all-optical switch has no RC time limits. The switching speed is limited only by the generated carrier lifetime, which is in the picosecond range. Being the basic building block for high-speed optoelectronic computing and signal processing, this generic concept is applicable to a broad variety of photonic components, including optical logic gates, EO modulators, variable delay lines, and crossbar reconfigurable interconnects. To optimize the switching efficiency, several optical switch designs were studied, including cross switches and directional coupler switches. To realize the multichannel optical switches, a compact self-aligned packaging technique was developed. An all-optical switch using a 0.8 micrometer pumping laser beam and a 1.3 micrometer probe beam was demonstrated, and efficiency as a function of pumping power and wavelength was studied. DTIC

PROCESSING AND PROPERTIES OF Ag-CLAD BI-2223 TAPES
U. Balachandran, A. N. Iyer, P. Haldar (Intermagnetics General Corp., Guilderland, NY.), and L. R. Motowidlo (IGC/Advanced Supercomputers, Inc., Waterbury, CT.) Nov. 1993 14 p Presented at the 6th US-Japan Workshop on Superconductivity, Houston, TX, 6-7 Dec. 1993
(Contract W-31-109-eng-38)
(DE94-004603; ANL/ET/CP-81211; CONF-931238-1) Avail: CASI HC A03/MF A01

We prepared partially reacted, polyphase, Pb-doped Bi-Sr-Ca-Cu-O (2223) powders by solid-state and wet-chemical routes. The calcined powders were characterized by thermal analysis, x-ray diffraction, and scanning electron microscopy. We then fabricated long lengths of flexible Ag-clad 2223 tapes by the powder-in-tube technique. Multifilamentary conductors have been prepared by stacking circular single-core Ag-sheathed superconductor rods into larger Ag tube and then drawing and rolling the tube to final size. The tapes were given appropriate heat treatment and the growth of the 2223 phase at each step of the heat treatment was studied. At 4.2 and 27 K, improved process conditions yielded transport critical current density (J(sub c)) values greater than 10(exp 5) A/sq cm at zero field; at 77 K, J(sub c) exceeded 4 x 10(exp 4) A/sq cm. Using a two-step rolling with an intermediate heat treatment, we have fabricated conductors approximately 70 m long. The J(sub c) value of these long conductors is approximately 2 x 10(exp 4) A/sq cm at 77 K in self field. Superconducting pancake coils were fabricated from the long-length tapes by the wind-and-react technique. DOE

KALMAN FILTERING OF NARROWBAND INTERFERENCE FROM DIRECT SEQUENCE SPREAD SPECTRUM COMMUNICATIONS SYSTEMS Ph.D. Thesis
Brian William Kozminchuk Aug. 1992 259 p
(ISBN-0-315-84011-0; CTN-94-61047) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A novel and viable interference excisor based on a Kalman filtering technique is presented. The behavior and performance of block and recursive least squares algorithms is examined for the case of single- and swept-tone interferers. An extended Kalman filtering technique is suggested for the latter case. The Kalman technique is compared to the lattice recursive least squares algorithm from the perspective of bit error rate performance, showing the 1-2 dB superiority of the Kalman approach. A theoretical bit error rate formula is developed for frequency modulation interference generated by a state space model. It is shown that phase noise at the Kalman filter output will set the limiting performance level along with signal distortion, and that the Kalman filter has more problems with narrowband Gaussian noise. In considering means of counteracting these effects, the most important is the addition of phase smoothing, which can result in performance improvements of up to 4-5 dB. An adaptive filtering scheme using the Kalman filter approach is also presented, in which one of its parameters is varied over time while monitoring a mean-squared error function in order to locate the optimum setting for the filter. Its performance for narrowband Gaussian noise is shown to be similar to that of the optimized nonadaptive case. Author (CISTI)

AN INTEGRATED DELTA-SIGMA BASED IIR FILTER M.S. Thesis
Dennis Kin-Wah Au 1993 103 p
(ISBN-0-315-83593-1; CTN-94-61038) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Delta-sigma based infinite impulse response (IIR) filters are a recently developed circuit technique for efficiently realizing IIR filters operating directly on oversampled delta-sigma modulated signals. The design and single-chip implementation of a fifth-order delta-sigma based IIR filter are described. The filter coefficients are fully programmable and with the use of a structure that is inherently scaled for dynamic range, good filter performance is maintained over a wide variety of transfer functions. To eliminate multi-bit multiplications, five second-order digital delta-sigma modulators were used and dynamic range improvement was obtained through the use of multi-bit quantizers in these modulators. The filter was implemented as a very large scale integration chip using 1.2 micron complementary metal oxide semiconductor technology, occupying an area of 4,355 by 5,962 square microns. Simulations indicate that the clock range should operate up to 45 MHz. Author (CISTI)

PULSE TRANSFORMER CHARACTERIZATION Final Report [KARAKTERISERING VAN DE PULSTRANSFORMATOR]
W. H. P. Mosterdijk Dec. 1992 31 p In DUTCH Sponsored by DWOO, The Hague, Netherlands, and TNO Defence Research, Delft, Netherlands Original contains color illustrations
(Contract A87/K/045)
(PML-1992-73; TD92-2408; ETN-94-94936) Copyright Avail: Issuing Activity (TNO-Prins Maurits Lab., P. O. Box 45, 2280 AA Rijswijk, Netherlands)

The pulse transformer at TNO PML-Pulse Physics, Delft, is characterized. It constitutes the final step of an energy compression system (Kapitza facility) which can amplify the current up to 24 times, and consists of a primary single layer winding of 24 turns enclosed in a secondary winding. There is a sine wave current source with adjustable frequencies for the characterization. The measurements show that the main inductances decrease and the ohmic resistances increase with increasing frequency, due to differential currents, skin and proximity effect, and parasitic currents induced in the aluminum secondary winding. From the measurements a coupling factor of 0.94 is calculated for 200 Hz, which is slightly below the design specification of 0.98. ESA

ULTRALINEAR WIDEBAND INTEGRATED CIRCUIT DESIGN M.S. Thesis
John Nisbet Jan. 1993 209 p
(ISBN-0-315-84130-3; CTN-94-61061) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The design of ultralinear wideband integrated circuits (IC's) is treated from three perspectives: system design concerns, modeling and simulation techniques, and circuit design considerations. The system design phase uses concurrent treatment of noise and distortion to produce an appropriate block-and-level description of hardware partitioning. Conventional SPICE models and analysis can be used for design, but accurate simulations must include modeling refinements such as component mismatches and thermal distortion. The ultralinear design techniques include the use of local feedback and feedforward, current-mode and translinear topologies, and a variety of layout techniques which reduce electrical and thermal mismatches. The design techniques are applied to produce a surface acoustic wave driver amplifier IC with 1/10 the cost, 1/5 the area, and 1/4 the power consumption of an equivalent discrete implementation. These techniques can easily be applied to faster bipolar processes to achieve wide bandwidth, superb linearity, and low power consumption. Author (CISTI)

ALL-OPTICAL GAIN SWITCHING OF ERBIUM-DOPED FIBRE AMPLIFIERS M.S. Thesis
Glenn Peter Cheney 17 Dec. 1992 140 p
(ISBN-0-315-84120-6; CTN-94-61057) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The gain switching characteristics of erbium-doped fiber amplifiers with signal wavelengths in the 1525-1550 nm range are examined. Short duration, high energy pulses at wavelengths within the signal bandwidth are used for rapid switching of the amplifier gain at the signal wavelength. Experimental results indicate that the switching time is governed by the pulse duration and pulse energy for switching pulses generated by a Q-switched erbium-doped fibre laser. Switchoff times on the order of 10 ns were observed. This is many orders of magnitude lower than the fluorescence lifetime of erbium ions in a glass host, which limits the switching speed of amplifiers controlled by pump power modulation alone. The dynamic range of switching, defined as the difference in the amplifier gain before and after switching, is determined by the amplifier gain and the peak power of the short-duration switching pulse. This report discusses activities of the Diagnostics and Microelectronics thrust area which conducts activities in semiconductor devices and semiconductor fabrication technology for programs at Lawrence Livermore National Laboratory. Our multidisciplinary engineering and scientific staff use modern computational tools and semi-conductor microfabrication equipment to develop high-performance devices. Our work concentrates on three broad technologies of semiconductor microdevices: (1) silicon on 3-5 semiconductor microelectronics, (2) lithium niobate-based and 3-5 semiconductor-based photonics, and (3) silicon-based micromachining for application to microstructures and microinstruments. In FY-92, we worked on projects in seven areas. The projects are described in this report: novel photonic detectors; a wideband phase modulator; an optoelectronic terahertz beam system; the fabrication of microelectrode electrochemical sensors; diamond heatsinks; advanced micromachining technologies; and electrophoresis using silicon microchannels. PARTITIONING STRUCTURAL VHDL CIRCUITS FOR PARALLEL EXECUTION ON HYPERCUBES M.S. Thesis
Kevin L. Kapp Dec. 1993 212 p
(AD-A274390; AFIT/GCE/ENG/93D-07) Avail: CASI HC A10/MF A03

Distributing simulations among multiple processors is one approach to reducing VHDL simulation time for large VLSI circuit designs. However, parallel simulation introduces the problem of how to partition the logic gates and system behaviors among the available processors in order to obtain maximum speedup. This research investigates deliberate partitioning algorithms that account for the complex inter-dependency structure of the circuit behaviors. Once an initial partition has been obtained, a border annealing algorithm is used to iteratively improve the partition. In addition, methods of measuring the cost of a partition and relating it to the resulting simulation performance are investigated. Structural circuits ranging from one thousand to over four thousand behaviors are simulated. The deliberate partitions consistently provided superior speedup to a random distribution of the circuit behaviors. DTIC

(AD-A274549; TR-93(3478)-1; SMC-TR-93-57) Avail: CASI HC A03/MF A01

A tunnel-diode RF detector failed in DMSP system-level testing. An investigation was initiated by the prime contractor (Aerojet) with the assistance of The Aerospace Corporation. Destructive physical analyses carried out by Aerospace's Electronics Technology Center and by a commercial laboratory at the direction of Aerojet revealed a number of problems in the manufacturing process. Aerojet and Aerospace personnel visited the manufacturers of the detector module and the diodes and made recommendations that reduced or eliminated many of these difficulties. A search of the literature indicated that mechanical stress in the mesa region of the tunnel diodes was known to cause degradation and further suggested that elevated-temperature exposure would effectively screen out defective devices. Aerospace recommended such a screen. The implementation of this screen and the measures taken to clean up the manufacturer's process have greatly improved the reliability of the tunnel-diode detectors. The efficacy of the steps taken has been demonstrated clearly by comparison of electrical test results on the old and the improved components. Some time after our evaluation of the DMSP diodes, Aerospace was asked by NASA to examine diodes from the same vendor used for detectors on the AMSU/A mission. DTIC

PROCESSING, FABRICATION, AND DEMONSTRATION OF HTS INTEGRATED MICROWAVE CIRCUITS, APPENDIX A
1993 27 p
(AD-A274600) Avail: CASI HC A03/MF A01

Electronics based on high transition temperature superconductive thin film materials is presently viable in some important niches, particularly in passive microwave circuits. Applications requiring Josephson junctions are impeded by the lack of reproducible junctions, but the junctions that can be produced are good candidates for the new Rapid Single Flux Quantum class of extremely fast digital circuits. Other devices that take advantage of the weak fluxoid pinning of some films are also promising, particularly the flux flow transistor. The availability of both Josephson and flux flow devices at 77 K invites exploration of hybrid technologies using HTS multi-chip modules supporting silicon CMOS chips and superconductive chips at the same time. The superconductive contribution to the emerging applications can result in significant performance advantages, particularly in remote sensing and communications. DTIC

The transfer of the compact range and target identification technology initiated under JSEP support for time domain studies continues to make large advances. The installation of a large compact reflector and a modern radar of our design has been completed for ASD at Wright Patterson Air Force Base. This system will have all of the sensitivity of the Mini Range reported last year and yet has a 14 ft quiet (or target) zone. The reflector includes all the most updated features of the ESL design. Dr. Brian Kent of ASD has expressed complete satisfaction with its performance. It is the range we would like to have, but can never afford. A large even more advanced compact range is currently being designed for NASA, Langley which is specifically being focused for measurements as low as 300 MHz. This new range will fit in a room 40 ft x 40 ft x 80 ft instead of the previously required 120 ft x 120 ft x 360 ft. The cost savings in this care are enormous. Our JSEP research continues to focus on electromagnetic related topics. DTIC

FERROELECTRIC FLUORIDE MEMORY FET DEVELOPMENT Interim Technical Report, Aug. 1990 - Jun. 1992
Donald R. Lampe Oct. 1993 111 p
(Contract N00014-90-C-0159)
(AD-A274341) Avail: CASI HC A06/MF A02

This Interim Technical Report covers the development and integration of Barium Magnesium Fluoride (BMF) ferroelectric thin films for incorporation into the gate dielectric of a metal-insulator-silicon field effect transistor, capable of functioning in a non-volatile, nondestructive-readout (NDRO) ferroelectric random access memory (FERRAM). Also provided is a detailed description of the test vehicles implemented for the study of fabrication process integration and optimization and the resultant properties of ferroelectric/(semiconductor) memory FET (FEMFET) and related structures. The BMF films were deposited by co-evaporation in ultra high vacuum from barium fluoride and magnesium fluoride effusion sources. A substrate temperature of 200 C during deposition followed by an anneal in hydrogen at 480 C resulted in polarization orientation closest to the preferred. Film samples exhibited polarization, Ps, as high as 4.55 micro-C/sq cm. The permittivity varied from a value of 9 at 5 kHz to 8.4 at 500 kHz. This compares closely with the average value of 10 reported for bulk single crystals. The ferroelectric switching speed of the thin film was approximately 45 nanoseconds. DTIC

SYMBOLIC MODEL CHECKING FOR SEQUENTIAL CIRCUIT VERIFICATION

J. R. Burch, E. M. Clarke, D. E. Long, K. L. McMillan, and D. L. Dill 15 Jul. 1993 49 p
(Contract F33615-90-C-1465; ARPA Order 4976)
(AD-A274375; CMU-CS-93-211) Avail: CASI HC A03/MF A01

The temporal logic model checking algorithm of Clarke, Emerson, and Sistla is modified to represent state graphs using binary decision diagrams (BDD's) and partitioned transition relations. Because this representation captures some of the regularity in the state space of circuits with data path logic, the authors are able to verify circuits with an extremely large number of states. This new technique is demonstrated on a synchronous pipelined design with approximately 5 x 10(exp 120) states. The model checking algorithm handles full CTL with fairness constraints. Consequently, the authors are able to express a number of important liveliness and fairness properties, which would otherwise not be expressible in CTL. Empirical results are given on the performance of the algorithm applied to both synchronous and asynchronous circuits with data path logic. DTIC

ENHANCED ADAPTIVE STATISTICAL FILTER PROVIDING IMPROVED PERFORMANCE FOR TARGET MOTION ANALYSIS NOISE DISCRIMINATION STATEMENT OF GOVERNMENT INTEREST Patent Application

Francis J. OBrien, inventor (to Navy), Marcus L. Graham, inventor (to Navy), and Kai F. Gong, inventor (to Navy) 22 Sep. 1993 18 p
(AD-D016039; US-Patent-Appl-SN-127145) Avail: CASI HC A03/MF A01

An adaptive statistical filter system for receiving a data stream comprising a series of data values from a sensor associated with successive points in time. Each data value includes a data component representative of the motion of a target and a noise component, with the noise components of data values associated with proximate points in time being correlated. The adaptive statistical filter system includes a prewhitener module, a plurality of statistical filters of different orders and a selection module. The prewhitener module receives the data stream from the sensor and generates a corrected data stream comprising a series of corrected data values each associated with a data value of the data stream, each including a data component and a noise component with the noise components of data values associated with proximate points in time being decorrelated. The plural statistical filters are coupled to receive the corrected data stream in parallel from the prewhitener. DTIC

DESIGN AND TEST OF A REGENERATIVE SATELLITE TRANSMULTIPLEXER M.S. Thesis

Kenny King-Ming Hung May 1993 194 p
(ISBN-0-315-85280-1; CTN-94-61104) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

In a multiple access scheme for regenerative satellite communications, the bulk frequency division multiple access (FDMA) uplink signal is demodulated on board the satellite and then remodulated for time division multiplexing (TDM) downlink transmission. Conversion from frequency to time division multiplex format requires that the uplink signal be frequency demultiplexed and each individual carrier be subsequently demodulated. For thin-route application which consists of a large number of channels with fixed data rate, multicarrier demodulation can be accomplished efficiently by a digital transmultiplexer (TMUX) using a fast Fourier transform processor followed by a bank of per-channel processors. A time domain description of the TMUX algorithm is derived which elucidates how the TMUX functions. The per-channel processor performs timing and carrier recovery for optimum and coherent data detection. Timing recovery is necessarily achieved asynchronously by a filter coefficient interpolation. Carrier recovery is performed using an all-digital phase-locked loop. The combination of both timing and carrier loops is investigated for a multi-user system. The performance of the overall system is assessed over a multi-user, additive white Gaussian noise channel for a bit energy to noise power spectral density ratio down to zero dB. Author (CISTI)

CHANNEL MODEL FOR AC ELECTRIC ARC

H. L. Larsen 2 Jun. 1993 48 p
(PB94-124591; STF34-A93113) Avail: Issuing Activity (National Technical Information Service (NTIS))

This report contains the results from calculations of free-burning AC electric arcs in argon. In order to calculate the arc current and arc voltage, the external electric circuit must be taken into consideration. The external circuit is modeled by an equivalent circuit consisting of an ideal AC voltage source, a loss resistance, and an inductance. The qualitative behavior of the current-voltage characteristic is in agreement with observed characteristics, but experimental data are necessary in order to check whether the calculated power loss is reasonable. Non-symmetry was modeled by introducing different anode and cathode falls in the two half periods. An attempt at taking into account different cathode current densities in the two half periods, depending on whether the electrode or silicon melt is cathode, did not give satisfactory results. Thermionic emission was assumed in both half periods, but this may not be the right mechanism when the silicon melt is cathode. The time delay of the AC arc compared to the DC case is modeled by a time constant. It was shown that this preset time constant must be in agreement with the mean 'mechanical' relaxation time in the arc in order to fulfill the energy balance. By updating the time constant until this is achieved, the time constant is eliminated as a parameter that must be chosen a priori. NTIS

TECHNICAL REPORT OF ISSP. SER. A, NO. 2688: SUPPRESSION OF HIGHER-ORDER MODES IN AN RF CAVITY BY RESISTIVE MATERIAL
Tadashi Koseki, Yukihide Kamiya, and Masaaki Izawa Jun. 1993 10 p
(ISSN 0082-4798)
(JTN-94-80574) Avail: CASI HC A02/MF A01

A new RF (Radio Frequency, 500 MHz) cavity which has a simple damped structure for the 1.5 GeV VUV (Vacuum Ultraviolet Rays) ring will be presented in this paper. The feature of the cavity design is that HOM's (Higher-Order Modes) propagate out from the cavity through the beam-duct with a large diameter and are absorbed in resistive parts in the duct. A low power measurement on a prototype model of the cavity has been carried out, and the Q-values of HOM's are confirmed to drastically reduce. Thus the coupled-bunch instabilities due to HOM's are expected to be sufficiently suppressed. Author (NASDA)

TRANSMITTANCE FLUCTUATIONS AND NON-LINEARITY IN RANDOM CHAINS IN THE PRESENCE OF APPLIED ELECTRIC FIELDS
Susil K. Manna, Prabhat K. Thakur (Bose Research Inst., Calcutta, India.), and Abhijit Mookerjee Jul. 1993 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-603665; IC-93/222) Avail: CASI HC A03 (US Sales Only)

Numerical investigations of transmittance fluctuations in disordered chains in the presence of external electric fields have been conducted. An almost constant fluctuation was obtained in a length scale smaller than the localization length. However, the value of the fluctuation in the plateau region is dependent on the external electric field and strength of disorder. The transmittance autocorrelation was also studied as a function of external electric field to probe nonlinearity in transmittance. DOE

THE ANALYSIS OF THERMAL AND 1/F NOISE IN MOS DEVICES, CIRCUITS AND SYSTEMS Ph.D. Thesis
Paul Arthur Layman 1989 252 p
(ISBN-0-315-57811-4; CTN-94-60983) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The deterministic and stochastic limits to decreasing the size of metal oxide semiconductor (MOS) devices are reviewed, focusing on thermal and 1/f noise. An existing compact circuit model is modified to include a new thermal noise model that includes channel length modulation and carrier heating. A 1/f noise model is also incorporated. These models show improvements over existing space models. Noise measurements are described and compared to the new models. Thermal and 1/f noise calculations are incorporated into a new two-dimensional device simulator which handles arbitrary structures and includes external bias resistors. Noise calculations are performed by characterizing thermal and 1/f noise on an elemental basis, then solving the transpose system to determine the total noise in the desired terminal current. A new damping method is proposed for use with Newton's method to solve the partial differential equations in the simulator, which uses a new triangular grid structure that allows direct refinement. A new refinement algorithm is presented along with an interactive grid generation program. The impact of noise at circuit level is examined analytically and numerically using a dynamic random access memory storage cell as a test vehicle. Several design considerations and tradeoffs are discussed and possible limits are introduced. Author (CISTI)

As semiconductor devices shrink towards dimensions comparable to the mean free path of electrons, their electrical characteristics become more and more dominated by the wavelike nature of electrons. Since electron waves in semiconductors and optical waves in dielectrics are similar in many respects, the theoretical models used for studying optical devices can be modified and applied to electron wave devices. A quantum directional coupler switch is studied as the electronic analogy of the optical directional coupler. Since the quantum directional coupler switch is believed to be capable of switching at very high speeds at extremely low power levels, it has potential application in many areas of electronics. In studying the electrical characteristics of this device, two different approaches were taken. First, an electron wave coupled mode theory was developed and applied to study the switching behavior of the device. This theory is formal and physically insightful, but its accuracy extends only as far as the number of modes used in the wave function expression. The second approach was an electron wave beam propagation method which is less insightful but numerically more accurate and rigorous. By using a combination of these methods, a good appreciation of the operation of the device can be obtained. CISTI

AN EFFICIENT AND ACCURATE GREEN'S FUNCTION ANALYSIS OF PACKAGED MICROWAVE INTEGRATED CIRCUITS Ph.D. Thesis
Reza Faraji-Dana 1993 137 p
(ISBN-0-315-84425-6; CTN-94-61069) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A field theoretical approach is developed for the analysis of monolithic microwave integrated circuits (MMIC's). The usual mixed potential integral equation with Galerkin's moment method is used, as well as the characteristic Green's function technique. The original structure is separated into three layered media surrounding the source from the three directions, and the spectral domain technique is then applied to each layer to find the respective characteristic Green's function. Combining these one-dimensional Green's functions in an integral form gives the spatial Green's function (SGF) for the original packaged structure. The integral form of the SGF is exact for variable separable structures. Prony's approximation can be used to evaluate the integral. Surrounding wall effects can be isolated from the original open microstrip structure, and this creates an efficient computer-aided design tool for predicting circuit performance. Experiments were also performed on a number of packaged microstrip circuits to verify the numerical results of the moment method. The validity of the Green's function was examined for non-separable structures. As a special case, the Green's function of a line current over a truncated slab was analyzed and a close agreement was found between the approximate Green's function method and a formally exact moment method. This report summarizes efforts to characterize the measurement of conductive mesh and smooth surfaces using proximity measurements for a dielectric resonator. The resonator operates in the HEM11 mode and is shown to have an evanescent field behavior in the vicinity of the sample surface, raising some question to the validity of measurements requiring near normal incidence on the material. In addition, the slow radial field decay outside of the dielectric resonator validates the sensitivity to the planar supporting structure and potential radiation effects. Though these concerns become apparent along with the sensitivity to the gap between the dielectric and the material surface, the basic concept of the material measurement using dielectric resonators has been verified for useful comparison of material surface properties. The properties, particularly loss, may be obtained by monitoring the resonant frequency along with the resonator quality factor (Q), 3 dB bandwidth, or the midband transmission amplitude. Comparison must be made to known materials to extract the desired data. Author

(DE94-701204; JAERI-M-93-065) Avail: CASI HC A03/MF A01

The effect of titanium conduit on the critical current in (Nb,Ti)3Sn cable-in-conduit conductors was investigated to obtain a high performance conductor which would be applied to large superconducting magnets such as those for fusion machines. Titanium has equivalent thermal contraction coefficient to that of (Nb,Ti)3Sn filaments, and it is expected by using titanium as the conduit to suppress degradation of critical current due to excess thermal prestrain on (Nb,Ti)3Sn filaments. Some titanium conduit sample conductors were made, and their critical current performance were measured together with some stainless steel (SUS316) and copper-nickel alloy (Cu-10Ni) conduit conductors. The experimental results indicated that the titanium conduit conductors had no critical current degradation due to thermal strain, whereas the stainless steel and copper-nickel alloy conduit conductors showed remarkable degradation on their critical current performance and greater degradation was observed with smaller void conductor. In conclusion, titanium is verified to be excellent conduit material for (Nb,Ti)3Sn cable-in-conduit conductors. DOE

(DE94-701207; JAERI-M-93-072) Avail: CASI HC A04/MF A01

A 40-kA Nb3Al conductor was developed for the toroidal field (TF) coils of the experimental fusion reactors. Presently, Nb3Sn is mainly used for high-field superconductor (more than 12 T) and is commercially available in a various type. On the other hand, the critical current (Ic) degradation of the Nb3Al was only 5% under an intrinsic axial strain of 0.4%, according to the experimental results. In case of Nb3Sn, the degradation was 30%. Therefore, it is shown that Nb3Al has excellent mechanical performance and it very useful for the toroidal field coil which is operated under large electromagnetic force. However, Nb3Al is not practical to use at present due to the difficulty of its fabrication. This conductor could be operated up to the current of 46 kA at an external field of 11.2 T, which was the required field of the TF coils in the International Thermonuclear Experimental Reactor (ITER). According to this development, Nb3Al will become a useful superconductor for large-scale, high-field application, such as the fusion machine. DOE

DRY ETCHING PROCESS DEVELOPMENT FOR SUBMICRON AND NANOMETER SEMICONDUCTOR DEVICES
V. Stepanov Jun. 1993 27 p
(PB94-133196; ISBN-951-22-1673-6) Avail: CASI HC A03/MF A01

The reactive ion etching of GaAs, AlGaAs, and Si was investigated for submicron and nanometer scale semiconductor structure processing. Different parameters were varied and studied to achieve the desired controllability and reproducibility of fabrication process. That included the estimation of the influence of power density, pressure, gas flow rate, and relative composition, as well as etching time on controllable etch rates and profiles, damage and roughness, and anisotropy and selectivity. The investigations of dry etching allowed the fabrication of GaAs and Si pillar structures with diameter less than 30 nm. NTIS

NUMERICAL SIMULATION OF TOMOGRAPHIC RECONSTRUCTION FOR THE STUDY OF TURBULENCE USING OPTICAL WAVEFRONT SENSOR MEASUREMENTS M.S. Thesis
Robert L. Johnson Dec. 1993 82 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273851; AFIT/GAP/ENP/93D-04) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The optical quality of a coherent beam passing through a turbulent flow layer can be severely degraded by phase errors. The principle goal of this research is to model the use of wavefront sensor measurements and computed tomography to reconstruct refractive index distributions of transparent objects for the study of turbulent flows. Tomography is the processing of measurements of one-dimensional line integrals through a two-dimensional function to reconstruct a two-dimensional estimate of the function. A least-squares wavefront phase reconstructor is modeled using Zernike polynomials and triangle functions as elementary functions for the reconstructor. Two tomographic reconstruction algorithms are implemented: (1) iterative reconstruction; and (2) filtered back-projection. Through numerical simulation, the effects of undersampling and limited wavefront sensor resolution are studied. Distorted wavefront data are generated by performing line integrals through known objects with different numbers and ranges of view angle. Wavefront reconstruction is applied using varying resolution. Two tomographic reconstruction methods are employed and comparisons are made with the original known objects. Results show that a least-squares wavefront reconstructor using triangle functions provides better results. Increasing the number and range of view angles generally improves the quality of the tomographic reconstruction. Furthermore, iterative tomographic reconstruction techniques prove superior when limited data are available. DTIC

VORTEX METHODS
A. J. Chorin Jun. 1993 65 p Presented at the Les Houches Summer School of Theoretical Physics, Les Houches, France, 28 Jun. - 30 Jul. 1993 Revised
(Contract DE-AC03-76SF-00098)
(DE94-003245; LBL-34124; CONF-9306196-1) Avail: CASI HC A04/MF A01

Vortex methods originated from the observation that, in incompressible inviscid flow, vorticity (or, more accurately, circulation) is a conserved quantity, as can be readily deduced from the absence of tangential stresses. Thus, if the vorticity is known at time $t = 0$, one can find the flow at a later time by simply following the vorticity. In this narrow context, a vortex method is a numerical method that follows vorticity. The author restricts himself in these lectures to a special class of numerical vortex methods, those that are based on a Lagrangian transport of vorticity in hydrodynamics by smoothed particles (blobs) and those whose analysis contributes to the understanding of blob methods. Blob methods started in the 1930's. DOE

THE HIGH REYNOLDS NUMBER FLOW THROUGH AN AXIAL-FLOW PUMP
W. C. Zierke, W. A. Straka, and P. D. Taylor Nov. 1993 267 p
(Contract N00039-92-C-0100)
(AD-A273844; ARL/PSU-TR-93-12) Avail: CASI HC A12/MF A03

The high Reynolds number pump (HIREP) facility at ARL Penn State has been used to perform a low-speed, large-scale experiment of the incompressible flow of water through a two-blade-row turbomachine. HIREP can involve blade chord Reynolds numbers as high as 6,000,000 and can accommodate a variety of instrumentation in both a stationary and a rotating frame of reference. The objectives of this experiment were as follows: to provide a database for comparison with three-dimensional, viscous (turbulent) flow computations; to evaluate the engineering models; and to improve our physical understanding of many of the phenomena involved in this complex flow field. The experimental results include a large quantity of data acquired throughout HIREP. A five-hole probe survey of the inlet flow 37.0 percent chord upstream of the inlet guide vane (IGV) leading edge is sufficient to give information for the inflow boundary conditions, while some static-pressure information is available to help establish an outflow boundary condition. DTIC

HYDRODYNAMICS, ACOUSTICS AND SCALING OF TRAVELING BUBBLE CAVITATION M.S. Thesis
Yan P. KuhndeChizelle 24 Sep. 1993 193 p
(Contracts N00014-91-J-1295; N00014-91-J-1426)
(AD-A273846; ENG-200-30) Avail: CASI HC A09/MF A03

Recent observations of the geometries of growing and collapsing bubbles over axisymmetric headforms have revealed the complexity of the 'microfluidmechanics' associated with these flows. Among the complex features observed were bubble to bubble interaction, cavitation noise generation and bubble interaction with the boundary layer which leads to the shearing of the underside of the bubble and alters the collapsing process. All of these previous tests were performed on small headform sizes. The focus of this research is to determine the dynamics governing the growth and collapse of traveling bubbles and to analyze the scaling effects due to variations in geometry size, Reynolds number, and cavitation number. For this effect, cavitating flows over Schiebe headforms of different sizes (5.08 cm, 25.4 cm, and 50.8 cm in diameter) were studied in the David Taylor Large Cavitation Channel (LCC). The scaling effects captured on high-speed film and electrode sensors as well as the noise signals generated during the collapse of the cavities are presented. DTIC

EXPERIMENTAL CONTRIBUTION TO THE STUDY OF SECONDARY FLOWS IN CENTRIFUGAL TURBOPUMP STATOR COMPONENTS Ph.D. Thesis [CONTRIBUTION EXPERIMENTALE A L'ETUDE DES ECOULEMENTS SECONDAIRES DANS LES ORGANES STATORIQUES DES TURBOPOMPES CENTRIFUGES]
Sahraoui Bouziane 1992 232 p In FRENCH Sponsored by SEP, France, and CNES Original contains color illustrations
(ECL-92-35; ETN-94-95279) Avail: CASI HC A11/MF A03

The flow characteristics in centrifugal turbomachines is investigated. Particular attention is given to the turbomachine stator components. The purposes of the study were: to validate the flow model for centrifugal turbopumps; to perform flow measurements on a test bed model in order to acquire accurate stator and U-bend pipe flow data; and to acquire local flow data for future numerical flow characterizations. The validity of the quasi three dimensional hypothesis is investigated. The characteristics of the low energy fluid accumulation zone are discussed. The effect of the stability of the blade root on the accumulation zone vortices is studied. The stator configuration choice is explained. The method applied for simulating the inducer's flow is described. The results of the flow visualization measurements showed that the outlet flow can be improved. ESA

EXPERIMENTAL ANALYSIS OF HEAT TRANSFER CHARACTERISTICS AND PRESSURE DROP THROUGH SCREEN REGENERATIVE HEAT EXCHANGERS M.S. Thesis
Jeffrey L. Wiese Dec. 1993 120 p
(AD-A273902; AFIT/GAE/ENY/93D-30) Avail: CASI HC A06/MF A02

This study investigated the effect on heat transfer and friction characteristics for screen regenerative heat exchangers with the screen thickness reduced by rolling. The experiments were performed on 250 and 325 mesh, 304 stainless steel screen using helium gas. Reynolds numbers, based on hydraulic radius, Re, were between 10 and 100. Both the Colburn factor, StPr(2/3), and friction factor, f, decreased as the screen thickness was reduced. A correlation was found for predicting friction factor, f. The drag coefficient per screen remained nearly unchanged for thicknesses reduced not more than 30 percent. The decrease in Colburn factor was significant for Re less than 40. For Re between 40 and 100 the decrease in Colburn factor was less than the experimental uncertainty. DTIC

Abstraction is shown to be an important concept to reduce complexity in parallel computing. The influence of abstraction on numerical software is demonstrated. It is shown that separating 'what, how, when, where', in other words separating a specification, its realization, and its implementation, has a lot of advantages. One advantage is that the obtained software has a clear and simple structure. Another advantage concerns portability, especially important in the field of parallel computing where no universal parallel computer model exists. In this area, software ought to be ported to other computer models easily. The investigation shows that a formal specification is a natural sequel to abstraction by discussing software development for a 1D (one dimensional) heat transfer problem. Aspects concerning formal verification are discussed. ESA

RIEMANN SOLVERS FOR SOLVING THE INCOMPRESSIBLE NAVIER-STOKES EQUATIONS USING THE ARTIFICIAL COMPRESSIBILITY METHOD
D. T. Elsworth and E. F. Toro Jun. 1992 25 p
(Cranfield-Aero-9208; ISBN-1-871564-549; ETN-94-95215) Avail: CASI HC A03/MF A01

Five Riemann solvers for the artificial compressibility equations are presented. The mathematical character of the artificial compressibility equations is introduced. The exact and the two rarefaction Riemann solvers are presented. The local linearization solver, the Roe solver, and the HLLC (Harten-Leer-Lax Riemann where the C stands for contact) solver are included. Riemann solvers for the split two dimensional artificial compressibility equations are presented. The results of numerical tests performed on the various Riemann solvers and conclusions are given. These solvers give accurate results when used to produce global solutions to the test problem. The rarefaction solvers are computationally expensive, and offer no special advantage over the other solvers. The linear solver is the cheapest computationally, is simple and accurate to use in a program to find the solution to the Navier-Stokes equations. The HLLC solver is also relatively cheap, and very robust. Under certain conditions it may be better to select this solver above the linear one. ESA

SHOCK WAVE INTERACTION WITH L-SHAPED STRUCTURES M.S. Thesis
Richard C. Miller Dec. 1993 104 p
(AD-A273774; AFIT/GAP/ENP/93D-07) Avail: CASI HC A06/MF A02

This study investigated the interaction of shock waves with L-shaped structures using the CTH hydrodynamics code developed by Sandia National Laboratories. Computer models of shock waves traveling through air were developed using techniques similar to shock tube experiments. Models of L-shaped buildings were used to determine overpressures achieved by the reflecting shock versus angle of incidence of the shock front. An L-shaped building model rotated 45 degrees to the planar shock front produced the highest reflected overpressure of 9.73 atmospheres in the corner joining the two wings, a value 9.5 times the incident overpressure of 1.02 atmospheres. The same L-shaped building was modeled with the two wings separated by 4.24 meters to simulate an open courtyard. This open area provided a relief path for the incident shock wave, creating a peak overpressure of only 4.86 atmospheres on the building's wall surfaces from the same 1.02 atmosphere overpressure incident shock wave. EFFECTS OF CRENULATIONS ON THREE DIMENSIONAL LOSSES IN A LINEAR COMPRESSOR CASCADE M.S. Thesis
William L. Spacy, II Dec. 1993 196 p
(AD-A273778; AFIT/GAE/ENY/93D-26) Avail: CASI HC A09/MF A03

An experimental investigation into the effect of compressor blade trailing edge geometry on three dimensional flows in a linear cascade was conducted at the AFIT linear cascade test facility. Hot-wire/hot-film anemometry along with total pressure instrumentation was used to analyze crenulation generated vortices and their interaction with the three dimensional flows in the cascade. The effects of this interaction on the performance parameters associated with the cascade were quantified. The results indicate that wake mixing is better for crenulated trailing edges and that the precise geometry of the crenulations is critical to performance. One crenulation geometry was found to increase wake mixing while slightly reducing the total pressure losses. DTIC

FLOW PAST A CIRCULAR CYLINDER WITH A PERMEABLE WAKE SPLITTER PLATE Annual Report, 1 Oct. 1992 - 30 Sep. 1993
Gregory S. Cardell 1 Aug. 1993 228 p
(Contract N00014-90-J-1589)
(AD-A273765) Avail: CASI HC A11/MF A03

Measurements in the near wake region of a circular cylinder in a uniform flow in the Reynolds number range 2.5 x 10(exp 3) is approximately less than Re is approximately less than 1.8 x 10(exp 4) with permeable splitter plates spanning the wake center plane are presented. Permeability is defined by the pressure drop across the plates, and the relationship between permeability and plate solidity is determined for a set of plates constructed from woven wire mesh permitting unambiguous characterization of the splitter plates by the solidity. The effects of different solidities on the flow in the near wake are investigated using smoke wire flow visualization, hot-wire anemometry, and measurements of the mean pressure at the cylinder surface, and the results are related to cylinder flow without a splitter plate. Flow visualization results demonstrate that the introduction of low solidity splitter plates does not change the basic near wake structure, and that sufficiently high solidity uncouples the large-scale wake instability from the body, with the primary vortex formation occurring downstream of the separation bubble due to instability of the wake profile. Hot-wire and surface pressure measurements confirm and quantify the flow visualization results, showing that the permeable splitter plates reduce the drag and modify the primary wake frequency. When the solidity is high enough that the wake is convectively unstable, the base pressure is independent of the Reynolds number and solidity. For a wide range of solidities, the same asymptotic value of the Strouhal number is reached at high Reynolds numbers. The relationship between the Strouhal number and the base pressure is discussed. WAKE PASSAGE EFFECTS ON THE LOSSES IN A LINEAR TURBINE CASCADE M.S. Thesis
James A. Braunschneider Dec. 1993 121 p
(AD-A273794; AFIT/GAE/ENY/93D-6) Avail: CASI HC A06/MF A02

A linear turbine cascade was used to investigate the effects of wake passage due to stator-rotor interaction. The wakes were modeled by passing 1.98 mm (0.078 in) diameter bars upstream of a linear cascade blade row. Total pressure loss coefficients, mass averaged total pressure loss coefficients, and velocities were used to characterize the effects of wake passage. Bar passing frequencies of 80, 160, 320 bars/sec were tested. These frequencies were tested, with the bars at 6.35 mm (0.25 in) intervals and at two Reynolds numbers, 341,000 and 455,000. Bar spacings of 12.7 mm (0.5 in), and 89 mm (3.5 in) were also examined. For a bar spacing of 12.7 mm these tests were made at a Reynolds number of 455,000 and bar passing frequencies of 80 bars/sec, 160 bars/sec, and with the bars stopped. The varying Reynolds numbers did not affect the results nor was there appreciable differences for the range of wake passing frequencies. However, for the same bar passing frequency, losses were effectively halved by doubling the spacing. The lack of influence of frequency and the effect of spacing was consistent with the time scale used. The maximum time scale reached was 0.95 so any influence due to changes in frequency were not felt in the blade passage. Whereas, for the same frequency, with half the bars, there were half the losses in the passage at any given time. DTIC

A NUMERICAL DETERMINATION OF BIFURCATION POINTS FOR LOW REYNOLDS NUMBER CONICAL FLOWS M.S. Thesis

Larry K. Waters Dec. 1993 78 p

(AD-A273984; AFIT/GAE/ENY/93D-29) Avail: CASI HC A05/MF A01

It has long been established that supersonic flow over axisymmetric conical bodies at high angles of attack tend to develop a side force due to vortical asymmetry. One of the proposed reasons for the asymmetry is a bifurcation point in the solution of the Navier-Stokes equations. This study investigated the possible existence of a bifurcation point in the Navier-Stokes equations for subsonic flow. Newton's method, with gauss elimination, was used-to solve the steady-state, viscous, compressible Navier-Stokes equations in spherical coordinates assuming conical similarity. DTIC

SHEAR FLOW GENERATION FROM THE INTERACTION OF NEOCLASSICAL AND DRIFT WAVE TRANSPORT PROCESSES

X. N. Su, P. N. Yushmanov, J. Q. Dong, and W. Horton Oct. 1993 49 p

(Contract DE-FG05-80ET-53088)

(DE94-003135; DOE/ET-53088/T4) Avail: CASI HC A03/MF A01

Self-consistent shear flow generation from the interaction of neoclassical and drift wave turbulence effects is investigated. The neoclassical poloidal flow damping is shown to compete with the flow generation driven by the divergence of the Reynolds stress. When there is no external driving force except for the free energy released from toroidal shear flow, the turbulent fluctuations occur as a transient pulse which takes the system along an equilibrium path to a relaxed state. External torques, such as parallel neutral beam injection, are needed to maintain significant fluctuation levels. For a system driven by a fixed ion temperature gradient, although linearly the poloidal shear flow generated substantially reduces the growth rate, the simulation results show that a sequence of nonlinear pulses occurs that eventually build the fluctuations up to a level that is not significantly affected by the poloidal flow. In this new, highly nonlinear state the transport is intermittent occurring through a sequence of pulses of duration 100 L(sub n)/c(sub s) for typical parameters. DOE

THE IDENTIFICATION OF INFLOW FLUID DYNAMICS PARAMETERS THAT CAN BE USED TO SCALE FATIGUE LOADING SPECTRA OF WIND TURBINE STRUCTURAL COMPONENTS

N. D. Kelley Nov. 1993 8 p Presented at the 13th Energy-sources Technology Conference and Exhibition (ETCE) on Wind Energy, New Orleans, LA, 23-26 Jan. 1994

(Contract DE-AC02-83CH-10093)

(DE94-000231; NREL/TP-442-6008; CONF-940113-5) Avail: CASI HC A02/MF A01

We have recently shown that the alternating load fatigue distributions measured at several locations on a wind turbine operating in a turbulent flow can be described by a mixture of at least three parametric statistical models. The rainflow cycle counting of the horizontal and vertical inflow components results in a similar mixture describing the cyclic content of the wind. We believe such a description highlights the degree of non-Gaussian characteristics of the flow. We present evidence that the severity of the low-cycle, high-amplitude alternating stress loads seen by wind turbine components are a direct consequence of the degree of departure from normality in the inflow. We have examined the details of the turbulent inflow associated with series large loading events that took place on two adjacent wind turbines installed in a large wind park in San Gorgonio Pass, California. In this paper, we describe what we believe to be the agents in the flow that induced such events. We also discuss the atmospheric mechanisms that influence the low-cycle, high-amplitude range loading seen by a number of critical wind turbine components. We further present results that can be used to scale the specific distribution shape as functions of measured inflow fluid dynamics parameters. DOE

EXPERIMENTAL AND NUMERICAL INVESTIGATION OF SHOCK WAVE PROPAGATION THROUGH COMPLEX GEOMETRY, GAS CONTINUOUS, TWO-PHASE MEDIA Ph.D. Thesis

J. Chien-Chih Liu (California Univ., Berkeley.) 1993 294 p

(Contract DE-AC05-76OR-00033)

(DE94-001408; DOE/OR-00033/T565) Avail: CASI HC A13/MF A03

The work presented here investigates the phenomenon of shock wave propagation in gas continuous, two-phase media. The motivation for this work stems from the need to understand blast venting consequences in the HYLIFE inertial confinement fusion (ICF) reactor. The HYLIFE concept utilizes lasers or heavy ion beams to rapidly heat and compress D-T targets injected into the center of a reactor chamber. A segmented blanket of failing molten lithium or Li2BeF4 (Flibe) jets encircles the reactors central cavity, shielding the reactor structure from radiation damage, absorbing the fusion energy, and breeding more tritium fuel. CHEMICAL AND VIBRATIONAL NONEQUILIBRIUM VISCOUS FLOWS: MODELLING, INTERNAL AND EXTERNAL FLOW APPLICATIONS

Cyril Flament (Office National d'Etudes et de Recherches Aerospatiales, Paris, France.) Aug. 1993 336 p Transl. into ENGLISH of Ecoulements de fluide visqueux en desequilibre chimique et vibrationnel: Modelisation, applications internes et externes (Paris, France, ONERA) 1991 p 1-276 Original language document was announced as N92-19221

(ESA-TT-1274; ONERA-NT-1991-2; ETN-94-95288) Avail: CASI HC A15/MF A03

A study aimed at the elaboration of a numerical code for solving chemical and vibrational nonequilibrium viscous flows is reported. This work includes the analysis and the use of several physical models (transport properties, thermodynamic functions, chemical kinetics, vibrational relaxation, and dissociation vibration coupling), the numerical analysis of equations with source terms (rendering implicit, Total Variation Diminishing (TVD) scheme), and applications to hypersonic flows for various nozzle and reentry body configurations. Quasimonodimensional Euler results are presented for the test nozzles R6 and F4, whose reservoir conditions are respectively, 50 bars, 4800K and 2000 bars, 8500K. Axisymmetric Navier-Stokes results for the flow around a sphere cylinder (Mach number M = 15.3) and around a hyperboloid (Mach number = 15.4) are detailed. The effects of each physical phenomenon (nonequilibrium, thermal conductivity, diffusion, vibration dissociation coupling) and numerical aspect (computational grid, averages) are studied. The results are in good agreement with those obtained by other calculations for both internal and external flows. ESA

PREDICTIVE MODELING OF PARTICLE-LADEN, TURBULENT FLOWS

Jennifer L. Sinclair, E. J. Bolio, and C. Hrenya 1993 29 p
(Contract DE-FG22-92PC-92540)
(DE94-003298; DOE/PC-92540/T3) Avail: CASI HC A03/MF A01

An Eulerian two-fluid mathematical model is considered for the flow prediction of gas-particle systems. The model expands on the Sinclair and Jackson model by recognizing a turbulent continuous phase. Both the gas- and the particle-phase velocity fields are composed of by a mean and a fluctuating component, and the important physical phenomena arising from the interaction of these components are included in the model. The gas turbulence is modeled by a single-phase closure, namely the k-(var epsilon) low Reynolds model by Myong and Kasagi, and modified to account for the presence of a dilute particle phase. The solid phase is considered as a rapid granular flow; hence, a closure based on the kinetic-theory analogy is used for the description of the stresses associated with this phase. Along with the relation between the fluxes of both phases and the pressure drop, the model is capable of predicting features related to the local flow structure, such as the mean and fluctuating velocity components and the concentration of both phases. In this report, the model is applied to the case of steady, fully developed flow in a vertical cylindrical pipe. An extensive comparison of the model predictions with experimental data is included. The sensitivity of the model predictions to the properties describing the particle collisions is also explored. DOE

POTENTIAL CAPABILITIES OF REYNOLDS STRESS TURBULENCE MODEL IN THE COMMIX-RSM CODE

F. C. Chang and M. Bottoni 1993 11 p Presented at the NASA 2003 Conference, Anaheim, CA, 7 Dec. 1993
(Contract W-31-109-eng-38)
(DE94-003716; ANL/ET/CP-79607; CONF-931235-3) Avail: CASI HC A03/MF A01

A Reynolds stress turbulence model has been implemented in the COMMIX code, together with transport equations describing turbulent heat fluxes, variance of temperature fluctuations, and dissipation of turbulence kinetic energy. The model has been verified partially by simulating homogeneous turbulent shear flow, and stable and unstable stratified shear flows with strong buoyancy-suppressing or enhancing turbulence. This article outlines the model, explains the verifications performed thus far, and discusses potential applications of the COMMIX-RSM code in several domains, including, but not limited to, analysis of thermal striping in engineering systems, simulation of turbulence in combustors, and predictions of bubbly and particulate flows. MIX INDUCED BY SINGLE SHOCK PASSAGE THROUGH A MATERIAL INTERFACE

V. C. Rupert, W. P. Crowley, and G. D. Kramer Jul. 1993 8 p Presented at the 19th International Sympsium on Shcok Waves, Marseille, France, 26-30 Jul. 1993
(Contract W-7405-eng-48)
(DE93-019505; UCRL-JC-114800; CONF-930788-4) Avail: CASI HC A02/MF A01

The question of perturbation growth at a shocked interface between materials with different densities has been studied in earnest in the last few years. The authors have been interested in the case of single-shock crossing the interface as a counterpart to the work done with one or several reflected waves. Using the LAM code the authors are systematically studying the interaction of a single shock with a wavy interface. During this first phase, they concentrated on the effect of the initial interface shape and on the Mach number dependence of the mixing process. Their simulations addressed a shock incident from a high-density gas into a low-density gas interface, and from a low-density gas onto a high-density gas interface. DOE

ON PREDICTION OF EQUILIBRIUM STATES IN HOMOGENEOUS COMPRESSIBLE TURBULENCE

Ridha Abid Mar. 1994 29 p
(Contract NAS1-19299; RTOP 505-70-62-15)
(NASA-CR-4570; NAS 1.26:4570) Avail: CASI HC A03/MF A01

Direct numerical simulations of compressible, homogeneous, turbulent shear flows are used to evaluate Reynolds stress models. Three pressure-strain models, which are either linear, quadratic, or cubic in the anisotropy tensor are considered. Dilatational dissipation and pressure-strain correlation models do not correctly capture the compressibility effects seen in the direct simulations. In particular, the increase in the anisotropy of normal stresses and the reduction in the shear stress are not reproduced by any of the models. Also, the use of the incompressible form of the dissipation-rate equation to determine the solenoidal part of the dissipation is found to be questionable. Author

A NUMERICAL STUDY OF QUANTIZED VORTICES IN HeII Ph.D. Thesis

Ronald Godfried Kari Aarts 1993 125 p Sponsored by Netherlands Organization for the Advancement of Scientific Research
(ISBN-9-03-860232-4; ETN-94-95340) Avail: CASI HC A06/MF A02

The numerical simulation of the motion of quantized vortices in a superfluid is discussed. These vortices play an important role in the flow properties of pure superfluid He-4 (He-II) and of (He-3)-(He-4) mixtures at low temperatures. The hydrodynamic properties of He II are described by the two fluid model in which the liquid is treated as a mixture of a normal component and a superfluid component. In flow experiments critical velocities are observed. The Schwarz reconnection vortex tangle model is applied. Numerical considerations involving the stability of the algorithm, and the choice of an accurate algorithm to solve the equation of motion of the vortices are included. Results of vortex tangle simulations are presented. ESA

THE NONLINEAR GALERKIN METHOD: A MULTI-SCALE METHOD APPLIED TO THE SIMULATION OF HOMOGENEOUS TURBULENT FLOWS Final Report

A. Debussche (Paris XI Univ., Orsay, France.), T. Dubois (Paris XI Univ., Orsay, France.), and R. Temam (Paris XI Univ., Orsay, France.) Dec.

1993 87 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191581; NAS 1.26:191581; ICASE-93-93) Avail: CASI HC A05/MF A01

Using results of Direct Numerical Simulation (DNS) in the case of two-dimensional homogeneous isotropic flows, the behavior of the small and large scales of Kolmogorov like flows at moderate Reynolds numbers are first analyzed in detail. Several estimates on the time variations of the small eddies and the nonlinear interaction terms were derived; those terms play the role of the Reynolds stress tensor in the case of LES. Since the time step of a numerical scheme is determined as a function of the energy-containing eddies of the flow, the variations of the small scales and of the nonlinear interaction terms over one iteration can become negligible by comparison with the accuracy of the computation. Based on this remark, a multilevel scheme which treats differently the small and the large eddies was proposed. Using mathematical developments, estimates of all the parameters involved in the algorithm, which then becomes a completely self-adaptive procedure were derived. Finally, realistic simulations of (Kolmorov like) flows over several eddy-turnover times were performed. The results are analyzed in detail and a parametric study of the nonlinear Galerkin method is performed. Author (revised)

HIGH RESOLUTION MEASUREMENTS OF MIXING AND REACTION PROCESSES IN TURBULENT FLOWS Annual Report, 1 Oct. 1992 - 31 Sep. 1993

W. J. Dahm 30 Nov. 1993 41 p
(Grant AF-AFOSR-0541-89)
(AD-A274970; AFOSR-94-0031TR) Avail: CASI HC A03/MF A01

Fully-resolved, two-, three-, and four-dimensional, spatio-temporal imaging measurements of the fine structure of conserved scalar mixing in turbulent flows are being used to identify new insights into molecular mixing and develop practical models for turbulent combustion. During the past year, the high wavenumber part of the scalar mixing spectrum was measured and appears to confirm the Batchelor model. However, the cutoff wavenumber is found to lie significantly lower than classical theory suggests. The first measurements of the distribution of dissipation layer separations in turbulent flows were also obtained. These results show a surprisingly simple and potentially insightful -3 power law scaling for scalar mixing that has not yet been explained. A new strained dissipation and reaction layer (SDRL) model was developed that relates the chemical state of nonequilibrium reaction chemistry to the mixing state of one or more conserved scalar fields. This model was coupled with our high resolution Rayleigh imaging measurements to predict combustion species concentration and reaction rate fields in turbulent reacting flows. Results from this model show striking agreement with direct species imaging measurements in turbulent combustion, and allow access to species that cannot be measured directly. This new physically-based formulation appears to unify the previous flamelet and distributed reaction models within a single model capable of treating even deep nonequilibrium combustion. DTIC

THE DYNAMICS OF INTERACTING NONLINEARITIES GOVERNING LONG WAVELENGTH DRIFTWAVE TURBULENCE Ph.D. Thesis

D. E. Newman Sep. 1993 107 p
(Contract DE-FG02-89ER-53291)
(DE94-001785; DOE/ER-53291/225) Avail: CASI HC A06/MF A02

Because of the ubiquitous nature of turbulence and the vast array of different systems which have turbulent solutions, the study of turbulence is an area of active research. Much present day understanding of turbulence is rooted in the well established properties of homogeneous Navier-Stokes turbulence, which, due to its relative simplicity, allows for approximate analytic solutions. This work examines a group of turbulent systems with marked differences from Navier-Stokes turbulence, and attempts to quantify some of their properties. This group of systems represents a variety of drift wave fluctuations believed to be of fundamental importance in laboratory fusion devices. From extensive simulation of simple local fluid models of long wavelength drift wave turbulence in tokamaks, a reasonably complete picture of the basic properties of spectral transfer and saturation has emerged. These studies indicate that many conventional notions concerning directions of cascades, locality and isotropy of transfer, frequencies of fluctuations, and stationarity of saturation are not valid for moderate to long wavelengths. In particular, spectral energy transfer at long wavelengths is dominated by the E x B nonlinearity, which carries energy to short scale in a manner that is highly nonlocal and anisotropic. In marked contrast to the canonical self-similar cascade dynamics of Kolmogorov, energy is efficiently passed between modes separated by the entire spectrum range in a correlation time. At short wavelengths, transfer is dominated by the polarization drift nonlinearity. While the standard dual cascade applies in this subrange, it is found that finite spectrum size can produce cascades that are reverse directed and are nonconservative in enstrophy and energy similarity ranges. In regions where both nonlinearities are important, cross-coupling between the nolinearities gives rise to large no frequency shifts as well as changes in the spectral dynamics. DOE

COMPUTATIONAL STRATEGIES FOR THREE-DIMENSIONAL FLOW SIMULATIONS ON DISTRIBUTED COMPUTER SYSTEMS Ph.D. Thesis Semiannual Status Report, 15 Aug. 1993 - 15 Feb. 1994

Richard Allen Weed and L. N. Sankar Mar. 1994 58 p
(Grant NAG2-869)
(NASA-CR-195249; NAS 1.26:195249) Avail: CASI HC A04/MF A01

An increasing amount of research activity in computational fluid dynamics has been devoted to the development of efficient algorithms for parallel computing systems. The increasing performance to price ratio of engineering workstations has led to research to development procedures for implementing a parallel computing system composed of distributed workstations. This thesis proposal outlines an ongoing research program to develop efficient strategies for performing three-dimensional flow analysis on distributed computing systems. The PVM parallel programming interface was used to modify an existing three-dimensional flow solver, the TEAM code developed by Lockheed for the Air Force, to function as a parallel flow solver on clusters of workstations. Steady flow solutions were generated for three different wing and body geometries to validate the code and evaluate code performance. The proposed research will extend the parallel code development to determine the most efficient strategies for unsteady flow simulations. Author (revised)

BEHAVIOUR OF SEPARATION BUBBLES IN SHARP-EDGED GAPS OF FINITE DIMENSIONS M.S. Thesis

Nathalie Hetu Apr. 1993 177 p
(ISBN-0-315-84113-3; CTN-94-61054) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Measurements are presented for the nominally two-dimensional flow in a sharp-edged gap with finite length and height, and complemented with extensive flow visualization. The gap geometry is seen to have a significant influence on both the streamwise and transverse dimensions of the two-dimensional separation bubble present at the gap inlet. The height and length of the bubble remain a constant proportion of the gap height for various values of the height/length ratio. However, in a slightly diffusing clearance gap, the flow remains separated throughout. The Reynolds number, varied from 150,000 to 325,000, was found to have no influence on the flow in the gap. The discharge coefficient was calculated at four clearances, showing a correlation between its value and the gap height/length ratio. An existing model of the flow through a two-dimensional gap with a leading edge separation bubble is examined in light of the presented data and expanded to evaluate the discharge coefficient at various clearances. A second expression is suggested which improves the prediction, and the discharge coefficients evaluated in this manner are compared to those calculated from measurements made in the tip gap of a planar cascade of turbine blades. Results suggest that the prediction model developed can provide reasonable estimates of the discharge coefficient in actual tip gaps. Author (CISTI)

The performance of turbine airfoils is usually predicted by empirical correlations, which however are inadequate for the case of airfoils with maximum thickness to chord ratio (MTCR) higher than 25 percent. Studies were conducted to create a data base from which the performance of turbine airfoils with a MTCR higher than 25 percent could be predicted. A planar cascade consisting of four airfoils was constructed to allow the investigation of the effect of the MTCR on the airfoil performance. Three airfoil sets with MTCR of 15.2 percent (baseline), 26.6 percent, and 48.2 percent were used. Measurements included surface Mach number distributions for the baseline airfoil, total pressure loss coefficients, and deviation angles for isentropic exit Mach numbers of 0.7 (design), 0.9, and 1.1. The effect of varying the inlet boundary layer thickness and free-stream turbulence level was also examined. The results showed that the 26.6 percent airfoil produced lower losses as predicted by the Kacker and Okapuu (1982) correlation. The introduction of turbulence produced a significant redistribution of losses in the exit plane. The secondary loss decreased as the leading edge diameter was increased. Except for the baseline blade where high under-turning in exit flow angle was observed, the airfoils showed a decrease in over-turning with increasing exit Mach number, as predicted by Ainley and Mathieson (1951). VALIDATED HEAT-TRANSFER AND PRESSURE-DROP PREDICTION METHODS BASED ON THE DISCRETE-ELEMENT METHOD. PHASE 2: TWO-DIMENSIONAL RIB ROUGHNESS

C. A. James (Mississippi State Univ., Mississippi State.), B. K. Hodge (Mississippi State Univ., Mississippi State.), and R. P. Taylor (Mississippi State Univ., Mississippi State.) May 1993 98 p
(Contract W-31-109-eng-38)
(DE94-002379; ANL/ESD/TM-55) Avail: CASI HC A05/MF A02

Surface roughness is a commonly used approach for enhancing the rate of heat transfer of surfaces, such as in heat-exchanger tubes. Because the improved thermal performance of roughened surfaces is at the expense of increased flow resistance (increased pressure drop or friction factor), accurate prediction techniques for determining the friction factors and Nusselt numbers for roughened surfaces are required if such features are to be considered as design options. This report presents the results of the second phase of a research program sponsored by Argonne National Laboratory to validate models for the prediction of friction factors and Nusselt numbers for fully developed turbulent flow in enhanced heat-exchanger tubes. The first phase was concerned with validating a roughness model for turbulent flow in tubes internally roughened with three-dimensional distributed roughness elements, such as sandgrains, spheres, hemispheres, and cones. The second phase is concerned with devising and validating methods for the prediction of friction factors and Nusselt numbers for turbulent flow in tubes internally roughened with repeated, two-dimensional ribs aligned perpendicular to the flow. The ribs are spaced sufficiently far apart that the leeward-side separated flow reattaches to the wall before again separating in order to negotiate the next rib. This heat-transfer enhancement mechanism is called the separation and reattachment mechanism, after Rabas (1989). This work is limited to rectangular rib shapes. DOE

COMPUTATION OF NON-ISENTROPIC INTERNAL FLOWS WITH VARIABLE DENSITY

E. Brizuela Nov. 1993 53 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A274848; ARL-TR-10; DODA-AR-007-102) Avail: CASI HC A04

A computational fluid dynamics code named MULTIFLOW-2D has been acquired and is being put into service for the numerical simulation of gas turbine-type combustors. Certain areas of the code were found to be in need of improvement for this application. The areas marked for improvement are as follows: (1) the grid generation algorithm; (2) the manner of discretization of the continuity and momentum equations; and (3) the treatment of the inlet boundary conditions. Improvements to these areas were developed and incorporated to the code, and the code functioning in non-reactive flows was tested by means of numerical experiments. Verification against physical experiments is planned. DTIC

NUMERICAL STUDIES ON THE DYNAMICS OF BUBBLE, TURBULENT, FREE SHEAR FLOWS: EFFECT OF THE INTER-PHASE COUPLING ON THE GLOBAL FLOW EVOLUTION Final Report, 1 Nov. 1990 - 31 Oct. 1993

Eckart Meiburg 23 Dec. 1993 42 p
(AD-A274521) Avail: CASI HC A03/MF A01

We use direct numerical simulations to analyze the evolution of a temporally growing two-dimensional free shear layer seeded with a dilute suspension of bubbles under gravity. The bubble concentrations are dilute enough so that bubble bubble interactions are negligible, but cumulative effects of bubbles alter the flow field. The evolution of the bubbles can then be determined by tracking many individual bubbles, and the flow field is advanced using the Navier-Stokes equations with a coupling term in the momentum equation representing the effect of the bubbles on the flow. We interpret the results in terms of the difference in the vorticity, bubble concentration, and pressure fields relative to the passive or one way coupled case. Due to the nature of the vorticity production mechanism, the net circulation is not affected by the bubbles, but local variations do occur, especially near the vortex center. In addition to the effect of the bubbles on the flow, the bubble field is also altered as a result of the two-way coupling. The location of bubble accumulation is shifted away from the vortex center and the magnitude of this accumulation is reduced relative to the passive case. DTIC

(AD-A274414) Avail: CASI HC A04/MF A01

This report is divided into four parts. Part-1 provides an introduction to plunging jet phenomena and summarizes the major findings of our previous research. Part-2 presents a summary of the major experimental findings obtained during at Rensselaer. Part-3 describes two proposed mechanisms responsible for air entrainment. Part-4 presents the results of two different numerical calculations, one using a Euler-Lagrangian approach and the other based on solving a full two-fluid model with a CFD code. Finally, Part-5 presents our conclusions and recommendations for future research. DTIC

NOMINALLY 2-DIMENSIONAL FLOW ABOUT A NORMAL FLAT PLATE Annual Report, 1 Oct. 1992 - 30 Sep. 1993

Derek Lisoski 1 Aug. 1993 104 p
(Contract N00014-90-J-1589)
(AD-A274472) Avail: CASI HC A06/MF A02

Towing tank and water channel experiments and a two-dimensional vortex element numerical model were used to study the forces experienced by a bluff flat plate set normal to a nominally two-dimensional flow. Intrinsic (small scale) and extrinsic (large scale) three-dimensional motions in the experimental flow were isolated and their separate and combined effects on forces and overall wake development were studied. Transient flow development starting from rest, as well as steady flow conditions, were investigated. A force balance was used to measure the unsteady lift and drag of vertically oriented models projecting through a free surface with various lower end conditions; simultaneous LIF flow visualizations imaged the structure of the vortices in the wake. Plate aspect ratio, lower end condition, and angle of attack were varied to effect changes in large scale three-dimensional motions, while changes in Reynolds number and Richardson number (flow stratification) modified the small scale three dimensionality intrinsic to the flow. TURBULENT BOUNDARY LAYER INNER-OUTER INTERACTIONS Final Report, 1 Aug. 1989 - 31 Dec. 1992

David Guy Bogard, Choon Lim Gan, and Atul Kohli 6 Dec. 1993 123 p
(Contract N00014-89-J-1701)
(AD-A274357) Avail: CASI HC A06/MF A02

A summary of work performed to study the interactions between the inner and outer regions of a turbulent boundary layer is presented. The interactions were studied by observing the response of the boundary layer to different perturbations. The inner region was modified by adding surface roughness, and the outer region suppressed using large eddy breakup (LEBU) devices. Velocity measurements were made with a three component LDV, a scanning LDV, and an X-type hot-film probe. The scanning LDV was developed to obtain continuous time history measurements of instantaneous velocity profiles down to $y+ = 10$. Details of the structure of bursts, sweeps, and shear layers over smooth and rough walls were determined using conditional sampling with simultaneous measurements from a detector probe and a mapping probe. This allowed the mapping of the complete three-dimensional structure of the three-component velocity field for these structures. Both single point detection, using quadrant and VITA techniques, and a unique spatially coherent structure detection technique were used. The spatial detection technique developed in this project takes advantage of the two-dimensional velocity field information obtained from the scanning LDV. DTIC

A PARALLEL COMPUTATIONAL FLUID DYNAMICS UNSTRUCTURED GRID GENERATOR M.S. Thesis

Deborah E. Davis Dec. 1993 86 p
(AD-A274129; AFIT/GCS/Eng/93D-05) Avail: CASI HC A05/MF A01

This research addressed the development of a parallel computational fluid dynamics unstructured grid generator using Delaunay triangulation. The generator is applied to simple elliptical and cylindrical two-dimensional bodies. The methodologies used included Watson's point insertion algorithm, Holmes and Snyder's point creation algorithm, a discretized surface definition, Anderson's clustering function, and a Laplacian smoother. The first version of the software involved a processor boundary exchange at the end of each iteration with no inter-processor communications during the iterations. The second version used inter-processor communication during each iteration instead of the boundary exchange. Version 1 demonstrated a speedup of 1.8 for some portions of the code, but proved to be unscalable for more than two nodes due to the interdependency of the triangular elements. The results of Version 2 were similar. Two distribution methodologies, a simple 360-degree distribution and recursive spectral bisection (RSB), were examined. For the initial grid distribution, the distribution generated by the RSB code would be similar to the distribution generated by the 360-degree methodology and would require significantly more time to execute. EXPERIMENTAL VERIFICATION OF TOMOGRAPHIC RECONSTRUCTION OF TURBULENT AIR FLOW STRUCTURE USING OPTICAL WAVEFRONT MEASUREMENTS M.S. Thesis

Bryon L. Pedersen Dec. 1993 65 p
(AD-A274392; AFIT/GEO/Eng/93D-01) Avail: CASI HC A04/MF A01

The performance of an aircraft based optical system is degraded by aero-optic turbulence. The varying index of refraction within the turbulent field causes phase perturbation in an optical wave. In order to compensate for aero-optic turbulence effects, the nature of the turbulence must be understood. Large scale, organized structure within the turbulence has been found to contribute significantly to the overall phase perturbation caused by a turbulent field. A unique approach was devised to determine the turbulence structure using tomographic reconstruction techniques. Tomography provides an excellent means to determine the underlying structure within a turbulent field. The tomographic reconstruction produces a three-dimensional index of refraction plot of the turbulent field, revealing the structure within the turbulent field. An experiment was designed to determine the feasibility of the tomographic technique for reconstructing the turbulence structure. An optical wave was propagated through a turbulent field. A shearing interferometer was used to measure the wave front of the perturbed optical wave. The wave front phase map provided the projection data for a tomographic reconstruction of the index of refraction of the turbulent field. The experimental results verified the feasibility of the tomographic technique. DTIC

The characteristics of approximate Riemann solvers were investigated such as those of Osher and Roe, which are used as a 'building block' for construction of modern shock-capturing schemes. Also a new approximate Riemann solver is proposed which is the result of an improved HLLEM (Harten Lax van Leer Einfeldt Modified) scheme, satisfying the positivity and entropy condition. The data obtained indicate that this new Riemann solver can be generalized for non-equilibrium flows such as a chemically reacting high temperature one. Author (NASDA)

NUMERICAL SIMULATION OF THE REIGNITION OF DETONATION BY REFLECTED SHOCKS

D. A. Jones, E. S. Oran, and M. Sichel Dec. 1992 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A274755) Avail: CASI HC A03

We study the diffraction and decay of a detonation wave which occurs when the detonation propagates past an increase in cross-sectional area in a rectangular detonation tube. The computations solve the time-dependent two-dimensional Euler equations using an operator split Flux-Corrected Transport algorithm in an Ar diluted stoichiometric H_2/O_2 mixture. Previous studies have shown that the initial effect is the decoupling of the reaction front from the shock and the formation of a decaying blast wave or bubble in the larger tube. The detonation may then continue to decay, or be reignited by reflection of the bubble off confining surfaces. In this paper, we focus on reignition by shock reflection. DTIC

A SECOND-ORDER SHOCK-ADAPTIVE GODUNOV SCHEME BASED ON THE GENERALIZED LAGRANGIAN FORMULATION M.S. Thesis

Claude Lepage 1993 140 p
(ISBN-0-315-84549-X; CTN-94-61073) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Application of the Godunov scheme to the Euler equations of gas dynamics, based on the Eulerian formulation of flow, smears discontinuities (especially sliplines) over several computational cells, while the accuracy in the smooth flow regions is of the order of a function of the cell width. Based on the generalized Lagrangian formulation (GLF), the Godunov scheme yields far superior results. By the use of coordinate streamlines in the GLF, the slipline (itself a streamline) is resolved crisply. Infinite shock resolution is achieved through the splitting of shock cells, while the accuracy in the smooth flow regions is improved using a nonconservative formulation of the governing equations coupled to a second order extension of the Godunov scheme. Furthermore, GLF requires no grid generation for boundary value problems and the simple structure of the solution to the Riemann problem in the GLF is exploited in the numerical implementation of the shock adaptive scheme. Numerical experiments reveal high efficiency and unprecedented resolution of shock and slipline discontinuities. CISTI

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF CONVERGING CYLINDRICAL SHOCK WAVES PROPAGATING IN NARROW CYLINDRICAL CHAMBERS M.S. Thesis

Gley Zitouni Sep. 1992 125 p
(ISBN-0-315-84694-1; CTN-94-61088) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The propagation and stability of converging cylindrical shocks produced in an annular shock tube equipped with a three increment area contraction were investigated for various cylindrical chamber widths and two annular shock Mach numbers of 1.26 and 1.44. The method of characteristics, integrated using the Hartree scheme, was employed to determine the shock Mach number and pressure-time variations in the cylindrical chamber. These numerical values were verified experimentally by employing a set of piezoelectric pressure transducers placed at five different locations. In narrow cylindrical chambers, a new test section was used to determine the boundary layer effect on the shock strength. For a cylindrical chamber width of 2.5 mm, experimental results were found to be in excellent agreement with the inviscid numerical solution. For smaller widths, an empirical equation of the shock Mach number variation was developed. Stability of the converging shocks was examined from the series of spark shadowgraphs taken near the geometric center. Author (CISTI)

RESEARCH ON BLUFF BODY VORTEX WAKES
Anatol Roshko, Anthony Leonar, and Morteza Gharib 1993 13 p
(Contract N00014-90-J-1589)
(AD-A273780) Avail: CASI HC A03/MF A01

The long-term objective is to enhance fundamental understanding of the near-wake dynamics of vortex-shedding bluff bodies and the resulting forces. It is desired to better understand the role of Reynolds number, the role of three dimensional effects, the effects of forcing and force history, and the role of body geometry. The report first summarizes the combined experimental, computational, and theoretical investigations. Results on the effects of both a steady and a periodic axial component of flow on a circular cylinder wake are then given. Derived from text

INFLUENCE OF IMPELLER SHROUD FORCES ON TURBOPUMP ROTOR DYNAMICS
J. P. Williams (Rockwell Space Operations Co., Houston, TX.) and Dara W. Childs *In its* Bulk-Flow Analysis, Part A 10 Dec. 1993 8 p Submitted for publication (For primary document see N94-27377 07-34)
Avail: CASI HC A02/MF A02

The shrouded-impeller leakage path forces calculated by Childs have been analyzed to answer two questions. First, because of certain characteristics or the results of Childs, the forces could not be modeled with traditional approaches. Therefore, an approach has been devised to include the forces in conventional rotordynamic analyses. The forces were found to be well-modeled with this approach. Finally, the effect these forces had on a simple rotor-bearing system was analyzed, and, therefore, they, in addition to seal forces, were applied to a Jeffcott rotor. The traditional methods of dynamic system analysis were modified to incorporate the impeller forces and yielded results for the eigenproblem, frequency response, critical speed, transient response, and an iterative technique for finding the frequency of free vibration as well as system stability. All results lead to the conclusion that the forces have little influence on natural frequency but can have appreciable effects on system stability. Specifically, at higher values of fluid swirl at the leakage path entrance, relative stability is reduced. The only unexpected response characteristics that occurred are attributed to the nonlinearity of the model. Author

COMPRESSIBILITY EFFECTS ON ROTOR FORCES IN THE LEAKAGE PATH BETWEEN A SHROUDED PUMP IMPELLER AND ITS HOUSING
Nhai The Cao *In its* Bulk-Flow Analysis, Part A 10 Dec. 1993 76 p
(For primary document see N94-27377 07-34)
Avail: CASI HC A05/MF A02

A modified approach to Childs' previous work on fluid-structure interaction forces in the leakage path between an impeller shroud and its housing is presented in this paper. Three governing equations consisting of continuity, path-momentum, and circumferential-momentum equations were developed to describe the leakage path inside a pump impeller. Radial displacement perturbations were used to solve for radial and circumferential force coefficients. In addition, impeller-discharge pressure disturbances were used to obtain pressure oscillation responses due to precessing impeller pressure wave pattern. Childs' model was modified from an incompressible model to a compressible barotropic-fluid model (the density of the working fluid is a function of the pressure and a constant temperature only). Results obtained from this model yielded interaction forces for radial and circumferential force coefficients. Radial and circumferential forces define reaction forces within the impeller leakage path. An acoustic model for the same leakage path was also developed. The convective, Coriolis, and centrifugal acceleration terms are removed from the compressible model to obtain the acoustics model. A solution due to impeller discharge pressure disturbances model was also developed for the compressible and acoustics models. The results from these modifications are used to determine what effects additional perturbation terms in the compressible model have on the acoustic model. The results show that the additional fluid mechanics terms in the compressible model cause resonances (peaks) in the force coefficient response curves. However, these peaks only occurred at high values of inlet circumferential velocity ratios greater than 0.7. The peak pressure oscillation was shown to occur at the wearing ring seal. Introduction of impeller discharge disturbances with $n = 11$ diametral nodes showed that maximum peak pressure oscillations occurred at nondimensional precession frequencies of $f = 6.4$ and $f = 7.8$ for this particular pump. Bolleter's results suggest that for peak pressure oscillations to occur at the wearing ring seal, the nondimensional excitation frequency should be on the order of $f = 2.182$ for $n = 11$. The resonances found in this research do not match the excitation frequencies predicted by Bolleter. At the predicted peak excitation frequencies given by Bolleter, the compressible model shows an attenuation of the pressure oscillations at the seal exit. The compressibility of the fluid does not have a significant influence on the model at low values of nondimensional excitation frequency. At high values of nondimensional frequency, the effects of compressibility become more significant. For the acoustic analysis, the convective, Coriolis, and centrifugal acceleration terms do affect the results to a limited extent for precession excitation and to a large extent for a pressure excitation when the fluid operates at relatively high Mach numbers. A RAPID-PRESSURE CORRELATION REPRESENTATION CONSISTENT WITH THE TAYLOR-PROUDMAN THEOREM MATERIALLY-FRAME-INDIFFERENT IN THE 2D LIMIT Final Report
J. R. Ristorcelli, J. L. Lumley (Cornell Univ., Ithaca, NY.), and R. Abid (High Technology Corp., Hampton, VA.) Jan. 1994 51 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191591; NAS 1.26:191591; ICASE-94-1) Avail: CASI HC A04/MF A01

A nonlinear representation for the rapid-pressure correlation appearing in the Reynolds stress equations, consistent with the Taylor-Proudman theorem, is presented. The representation insures that the modeled second-order equations are frame-invariant with respect to rotation when the flow is two-dimensional in planes perpendicular to the axis of rotation. The representation satisfies realizability in a new way: a special ansatz is used to obtain analytically, the values of coefficients valid away from the realizability limit: the model coefficients are functions of the state of the turbulence that are valid for all states of the mechanical turbulence attaining their constant limiting values only when the limit state is achieved. Utilization of all the mathematical constraints are not enough to specify all the coefficients in the model. The unspecified coefficients appear as free parameters which are used to insure that the representation is asymptotically consistent with the known equilibrium states of a homogeneous sheared turbulence. This is done by insuring that the modeled evolution equations have the same fixed points as those obtained from computer and laboratory experiments for the homogeneous shear. Results of computations of the homogeneous shear, with and without rotation, and with stabilizing and destabilizing curvature, are shown. Results are consistently better, in a wide class of flows which the model not been calibrated, than those obtained with other nonlinear models. Author

Phenomenological models for use in the 'direct simulation Monte Carlo' method are studied. Emphasis is given to the modeling of chemical reactions. The use of these models is enhanced due to new computational techniques allowing, for example, a more efficient movement of particles in structured and unstructured grids. The drag of a cylinder in the transitional regime of cold hypersonic flows is calculated, and detailed comparisons to an experiment are made. The hypersonic flow with chemical reactions past a cylinder is simulated. Available nonequilibrium Navier-Stokes results for the same flow are used for comparison. The influence of chemical reactions on the wake structure behind the cylinder is also investigated. ESA

AN IMPROVEMENT IN THE MODIFIED FINITE ELEMENT PROCEDURE FOR UNDERWATER SHOCK ANALYSIS
S. K. Chan 1992 12 p Presented at the 63rd Shock and Vibration Symposium, Las Cruces, NM, 27 Oct. 1992
(Contract DE-AC11-93PN-38195)
(DE94-004451; WAPD-T-2956; CONF-9210176-6) Avail: CASI HC A03/MF A01

The modified finite element procedure for underwater shock analysis decomposes the total pressure field into the incident, reflected, and radiated pressure. The incident pressure is calculated by using a closed form solution. The reflected and radiated pressure are calculated in two separate finite element analyses. Artificial damping is added in the finite element analyses. Since these two pressures are generated from the fluid-structure interface and mostly propagate away from the interface, the artificial damping has no significant effect on the result. The modified finite element procedure was developed using a displacement formulated finite element to model the fluid region. In the paper, a pressure formulated finite element is used to model the fluid region which has a potential of saving 90 percent of the computer time. In doing so, the reflected and radiated pressure are calculated in one analysis which greatly simplifies the analysis procedure and saves more computer time. Two verification examples are given. DOE

THERMOCAPILLARY FLOW WITH EVAPORATION AND CONDENSATION AND ITS EFFECT ON LIQUID RETENTION IN LOW-G FLUID ACQUISITION DEVICES Final Report
George R. Schmidt Washington Feb. 1994 268 p Sponsored by NASA, Washington
(Proj. 91-15)
(NASA-TP-3463; M-743; NAS 1.60:3463) Avail: CASI HC A12/MF A03

The steady motion, thermal and free surface behavior of a volatile, wetting liquid in microgravity are studied using scaling and numerical techniques. The objective is to determine whether the thermocapillary and two-phase convection arising from thermodynamic nonequilibrium along the porous surfaces of spacecraft liquid acquisition devices could cause the retention failures observed with liquid hydrogen and heated vapor pressurant. Why these devices seem immune to retention loss when pressurized with heated helium or heated directly through the porous structure was also examined. Results show that highly wetting fluids exhibit large negative and positive dynamic pressure gradients towards the meniscus interline when superheated and subcooled, respectively. With superheating, the pressure variation and recoil force arising from liquid/vapor phase change exert the same influence on surface morphology and promote retention. With subcooling, however, the pressure distribution produces a suction that degrades mechanical equilibrium of the surface. This result indicates that thermocapillary-induced deformation arising from subcooling and condensation is the likely cause for retention loss. In addition, increasing the level of nonequilibrium by reducing accommodation coefficient suppresses deformation and explains why this failure mode does not occur in instances of direct screen heating or pressurization with a heated inert gas. Author (revised)

MACH REFLECTION OF SPHERICAL DETONATION WAVES
L. M. Hull 1993 9 p Presented at the 2nd Probabilistic Safety Assessment and Management Conference (PSAM), San Diego, CA, 20-24 Mar. 1994
(Contract W-7405-eng-36)
(DE93-016604; LA-UR-93-2080; CONF-940312-4) Avail: CASI HC A02/MF A01

When two detonation waves collide, the shape of the wave front at their intersection can be used to categorize the flow as regular or irregular reflection. In the case of regular reflection, the intersection of the waves forms a cusp. In the case of irregular reflection, the cusp is replaced by a leading shock locus that bridges the incident waves. Many workers have studied irregular or Mach reflection of detonation waves, but most of the their experimental work has focused on the interaction of plane detonation waves. Reflection of spherical detonation waves has received less attention. This study also differs from previous work in that the focus is to measure the relationship between the detonation velocity and the local wave curvature for irregular reflection of spherical detonation waves. Two explosives with different detonation properties, PBX 9501 and PBX 9502, are compared. DOE

MODELLING THE MASS MIGRATION PHENOMENA IN PARTIALLY FROZEN HEAT PIPES
Michael D. Keddy, Michael A. Merrigan, and Eric Critchley (Phillips Lab., Kirtland AFB, NM.) 1993 6 p Presented at the 11th Symposium on Space Nuclear Power Systems, Albuquerque, NM, 9-13 Jan. 1994
(Contract W-7405-eng-36)
(DE94-002716; LA-UR-93-3651; CONF-940101-16) Avail: CASI HC A02/MF A01

Liquid metal heat pipes operated at power throughputs well below their design point and with sink temperatures below the freezing temperature of the working fluid may fail as a result of the working fluid migrating to a cold region within the pipe, freezing there, and not returning to the evaporator section. Eventually, sufficient working fluid inventory may be lost to the cold region to cause a local dry-out condition in the evaporator. A joint

experimental and analytical effort by the Air Force Phillips Laboratory and Los Alamos National Laboratory is underway to investigate this phenomena. This paper presents an analytical model developed to describe this phenomena. The model provides for analytic determination of heat pipe temperature profiles, freeze-front locations and mass migration rates.

NUMERICAL SIMULATION OF RECEPTIVITY AND TRANSITION IN A BOUNDARY LAYER ON A FLAT PLATE WITH A SUCTION HOLE Final Report

Hermann F. Fasel Mar. 1994 22 p
(Contract NCC1-1422; NAG1-1433)
(NASA-CR-195708; NAS 1.26:195708) Avail: CASI HC A03/MF A01

A Navier-Stokes solver has been modified to allow for unsteady boundary conditions to be imposed at the inflow boundary. Because the streamwise derivatives are discretized with three-point compact differences, there is no need for special treatment of the points adjacent to the inflow boundary, provided that all necessary derivatives are properly specified at the boundary points. The unsteady boundary conditions can be obtained from a previous computation, from a solution of the parabolized stability equations (PSE), or from an analytical exact or approximate solution of the Navier-Stokes equations, e.g. an asymptotic expansion solution to model a sound wave interacting with the boundary layer. TIME-STEP ENLARGEMENT AND OPTIMAL SMOOTHING IN RUNGE-KUTTA TIME-INTEGRATION ALGORITHMS BY IMPLICIT AND EXPLICIT SMOOTHING

R. C. A. Linders 26 Jun. 1992 85 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NLR-TP-92221-U; ETN-94-95449; AD-B176008) Avail: CASI HC A05

Runge-Kutta (RK) time integration schemes are used in many industrial codes for the computation of steady flows, using the Euler and Navier-Stokes equations. For equations with diffusion, the maximum time step in a RK scheme is of O(h squared). A technique to enlarge the maximum time step to O(h) for diffusion convection equations is presented. This is achieved by applying an implicit smoothing operator to the residues in the RK scheme. An explicit smoothing operator, tuned to the implicit smoothing operator, is also needed, to obtain optimal high frequency damping. A four stage RK scheme is used to illustrate the technique. The ability to represent shock waves, with a four stage RK scheme with implicit and explicit smoothing, is demonstrated using the Burgers' equation. ESA

FLOWFIELD DYNAMICS IN BLUNT FIN-INDUCED SHOCK WAVE/TURBULENT BOUNDARY LAYER INTERACTIONS Final Report, 13 Mar. 1989 - 9 Nov. 1993

David S. Dolling and Leon Brusniak Jan. 1994 83 p
(Grant NAG3-1023)
(NASA-CR-195170; NAS 1.26:195170) Avail: CASI HC A05/MF A01

Fluctuating wall pressure measurements have been made on centerline upstream of a blunt fin in a Mach 5 turbulent boundary layer. By examining the ensemble averaged wall pressure distributions for different separation shock foot positions, it has been shown that local fluctuating wall pressure measurements are due to a distinct pressure distribution, Rho(sub i), which undergoes a stretching and flattening effect as its upstream boundary translates aperiodically between the upstream influence and separation lines. The locations of the maxima and minima in the wall pressure standard deviation can be accurately predicted using this distribution, providing quantitative confirmation of the model. This model also explains the observed cross-correlations and ensemble average measurements within the interaction. Using the Rho(sub i) model, wall pressure signals from under the separated flow region were used to reproduce the position-time history of the separation shock foot. Further, the negative time delay peak in the cross-correlation between the predicted and actual shock foot histories suggests that the separated region fluctuations precede shock foot motion. The unsteady behavior of the primary horseshoe vortex and its relation to the unsteady separation shock are described. Author (revised)

GRAVITY DEPENDENCE OR PRESSURE DROP AND HEAT TRANSFER IN STRAIGHT TWO-PHASE HEAT TRANSPORT SYSTEM CONDENSER DUCTS

A. A. M. Delil 21 Apr. 1992 16 p Presented at the 22nd International Conference on Environmental Systems Thermal Control Technology 1 Session, Seattle, WA, 13-16 Jul. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NLR-TP-92167-U; ETN-94-95445) Avail: CASI HC A03

Condensers are crucial components of two phase heat transport systems envisaged for future large spacecraft. To properly design such condensers, experimental data, obtained from ground testing and reduced gravity aircraft and rocket flight testing, plus results of thermal modeling and scaling calculations, are used. A frequently reported result of such activities is that condensation lengths required in low gravity environment exceed the corresponding lengths on earth, in horizontal ducts, up to one order of magnitude and more, while the accompanying pressure drops are almost the same. Since the flow patterns are different in the two situations, it is better to theoretically, and experimentally, investigate the impact of gravity on condensation pressure drops and heat transfer for an identical flow pattern, namely annual-wavy-mist, observed along almost the entire condensation length for vapor qualities ranging from close to 1 down to values below 0.1, both in low gravity environment and in vertical downflow in a gravity field. Within the validity range of the model used the impact of gravitation on condenser pressure drop and full condensation length is shown to be manifest for two different working fluids, ammonia and R114, and various duct diameters and thermal loading conditions (the power transported, the operating and sink temperatures). NEW CONSTITUTIVE EQUATION FOR THE VOLUME VISCOSITY IN FLUIDS

Allan J. Zuckerwar and Robert L. Ash (Old Dominion Univ., Norfolk, VA.) Mar. 1994 21 p Prepared for presentation at the 127th Meeting of the Acoustical Society of America, Cambridge, MA, 6-10 Jun. 1994
(RTOP 505-59-54-02)
(NASA-TM-109104; NAS 1.15:109104) Avail: CASI HC A03/MF A01

The traditional volume viscosity, Stokes' hypothesis, and acoustical relaxation are reviewed. The lossy Navier-Stokes Equation is applied to periodic (acoustic) flow, and it is shown that the traditional volume viscosity leads to a result which contradicts that describing acoustical relaxation. It is demonstrated that the addition of a second volume viscosity term to the constitutive equation, to account for pressure relaxation, resolves the conflict, and leads to a direct correspondence between the volume viscosity parameters and the acoustical relaxation parameters. The representation of volume viscosity is formulated for the case of multiple relaxations, as occur in air. Finally, an application of the new constitutive equation to a simple convective compressible flow, namely a linearly accelerating flow, demonstrates the impact of volume viscosity upon the flow and the physical conditions for which it is important. CIRCULAR CYLINDER IN AXIAL FLOW Ph.D. Thesis

Stephen P. Sawchuk Aug. 1990 280 p
(ISBN-0-315-59114-5; CTN-94-60993) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The boundary layer formed on the outer surface of a semi-infinite cylinder in steady axial incompressible flow is studied. Governing equations are solved using local similarity techniques and a nonsimilar numerical approach. Two similarity transformations can be used to obtain solutions. In the extreme case when the cylinder radius is much larger than the boundary layer thickness, only one of the transformations leads to the correct solution, the Blasius solution. The other transformation yields an axial velocity profile deceptively close to the Blasius. Solutions obtained by either transformation merge at downstream locations. An overall numerical solution is obtained by applying Keller's box method with primitive variables and similarity coordinates. Similarity coordinates scale the axial and radial coordinates such that the boundary layer growth does not appear explicitly as one moves downstream. Thus, the numerical mesh does not need to be enlarged and this leads to increased computational efficiency. Results are obtained in the range that starts with the Blasius solution and proceed far downstream. A local similarity method is also applied to obtain solutions valid over a wide range of flow. Results obtained by these methods compare well with previously obtained solutions but extend the range of solution considerably. Author (CISTI)

TVD FLUX-DIFFERENCE SPLIT METHODS FOR HIGH-SPEED THERMOCHEMICAL NONEQUILIBRIUM FLOWS WITH STRONG SHOCKS
Clinton P. T. Groth Dec. 1993 250 p
(ISSN 0082-5255)
(UTIAS-350) Copyright Avail: Issuing Activity

This study is concerned with the numerical solution of high-speed nonequilibrium gaseous flows with strong shocks. The extension of modern total-variation-diminishing (TVD) shock-capturing schemes to include thermochemical nonequilibrium high-temperature effects is of primary interest. Partially decoupled upwind-based TVD flux-difference split schemes for the solution of the conservation laws governing two-dimensional nonequilibrium vibrationally relaxing and chemically reacting flows of thermally-perfect gaseous mixtures are presented. Both time-split semi-implicit and factored implicit flux-limited TVD upwind schemes are described. The semi-implicit formulation is more appropriate for unsteady applications whereas the factored implicit form is useful for obtaining steady-state solutions. As well, a multigrid version of the fully implicit TVD scheme is also proposed for the more efficient computation of time-invariant solutions. The multigrid algorithm is based on the full approximation storage (FAS) and full multigrid (FMG) concepts and employs the partially-decoupled factored implicit scheme as the smoothing operator in conjunction with a four-level V-cycle coarsegrid-correction procedure. In the proposed methods, a novel partially-decoupled flux-difference splitting approach is adopted. The fluid conservation laws and the finite-rate species concentration and vibrational energy equations are decoupled by means of a frozen flow approximation. The resulting partially-decoupled gas dynamic and thermodynamic subsystems are then integrated alternately in lagged manner within a two-stage time marching procedure, thereby providing explicit coupling between the two equations sets. Extensions of Roe's approximate Riemann solvers, giving the eigenvalues and eigenvectors of the fully coupled systems, are used to evaluate the numerical flux functions. Additional modifications to the Riemann solutions are also described which ensure that the approximate solutions are not aphysical. Moreover, concerns associated with the satisfaction of monotonicity, positivity, and maximum principles are addressed. The proposed partially-decoupled methods are shown to have some computational advantages over chemistry-split and fully coupled techniques in coping with large systems of equations with stiff source terms. The predictive capabilities of the shock-capturing methods are demonstrated and their usefulness appraised, by solving a number of different flows with both complicated shock structure and complex nonlinear wave interactions. The problems considered include nonstationary oblique shock-wave reflections and diffractions and steady high-speed nozzle, compression ramp, and blunt-body flows. The numerical results are compared to available experimental data in many cases. Author

SUPERFLUID HELIUM SLOSHING DYNAMICS INDUCED OSCILLATIONS AND FLUCTUATIONS OF ANGULAR MOMENTUM, FORCE AND MOMENT ACTUATED ON SPACECRAFT DRIVEN BY GRAVITY GRADIENT OR JITTER ACCELERATION ASSOCIATED WITH SLEW MOTION Final Report
R. J. Hung Feb. 1994 106 p
(Contract NAS8-38609)
(NASA-CR-193928; NAS 1.26:193928) Avail: CASI HC A06/MF A02

The generalized mathematical formulation of sloshing dynamics for partially filled liquid of cryogenic superfluid helium II in dewar containers driven by the gravity gradient and jitter accelerations associated with slew motion for the purpose to perform scientific observation during the normal spacecraft operation are investigated. An example is given with the Advanced X-Ray Astrophysics Facility-Spectroscopy (AXAF-S) for slew motion which is responsible for the sloshing dynamics. The jitter accelerations include slew motion, spinning motion, atmospheric drag on the spacecraft, spacecraft attitude motions arising from machinery vibrations, thruster firing, pointing control of spacecraft, crew motion, etc. Explicit mathematical expressions to cover these forces acting on the spacecraft fluid systems are derived. The numerical computation of sloshing dynamics is based on the non-inertia frame spacecraft bound coordinate, and solve time-dependent, three-dimensional formulations of partial differential equations subject to initial and boundary conditions. The explicit mathematical expressions of boundary conditions to cover capillary force effect on the liquid-vapor interface in microgravity environments are also derived. The formulations of fluid moment and angular moment fluctuations in fluid profiles induced by the sloshing dynamics, together with fluid stress and moment fluctuations exerted on the spacecraft dewar containers have also been derived. Examples are also given for cases applicable to the AXAF-S spacecraft sloshing dynamics associated with slew motion. Author

THE NUMERICAL CALCULATION OF LAMINAR AND TURBULENT FLOWS USING PENALTY FUNCTION FINITE VOLUME METHODS Ph.D. Thesis
Jacques Simoneau Oct. 1990 279 p
(ISBN-0-315-61377-7; CTN-94-61001) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Two new algorithms are presented for calculating both laminar and turbulent flows. These algorithms are developed using finite volume methods but achieve pressure velocity coupling via penalty function methods. First, a sequential approach is introduced, where the penalized momentum equations are solved in a segregated manner. Various formulations for the coefficient and source terms are tested and the best one is identified. Second, a coupled approach is derived in which all momentum equations are solved simultaneously. Various solvers are tested and an efficient algorithm is identified. Preliminary tests reveal that the penalty approach is robust and requires no under relaxation of the momentum equations. The velocity and pressure fields do not suffer from modification of the continuity equation, and results are as accurate as those obtained using SIMPLE type algorithms. The sequential method is found to be slow but, when an appropriate solver is used, the coupled approach is faster than SIMPLE type algorithms. The coupled algorithm is fully tested, and its performance is compared with the SIMPLEC algorithm for four two-dimensional laminar and turbulent flows. The coupled method is, on average, about twice as fast as SIMPLEC. Author (CISTI)

The 37 papers prepared for the AGARD Fluid Dynamics Panel (FDP) Symposium on Computational and Experimental Assessment of Jets in Cross Flow are included. The primary objective of the Symposium was to provide a forum for assessing advances made in the technology and application of jets in cross flow which have occurred since the last meeting on this subject. Major topics covered included enhanced descriptions of the fundamental flow structure of jets in cross flow, experimental methods, thrust vectoring, jet impingement and exhaust gas reingestion, hypersonic crossflow, and numerics and turbulence modeling. For individual titles, see N94-28004 through N94-28040.

The jet in cross flow (JICF) is a basic flowfield which is relevant to a wide variety of applications which are described to provide context for JICF investigations. Material consistent with the scope of topics presented at the 72nd AGARD Fluid Dynamics Panel Meeting and Symposium on Computational and Experimental Assessment of Jets in Cross Flow on 19-22 April 1993 in Winchester, U.K. is summarized. The JICF research was divided into three time periods: (1) early research - up to 1970, (2) research during the 1970's, and (3) research since 1980. The following areas of experimental activity are discussed; the definition of an effective correlation parameter; the jet flowfield including the jet trajectories, cross-section shape, and jet induced pressures; the effects of jet deflection angle, nozzle shape, pressure ratio, velocity decay, and temperature; and the effect of confined flowfield, ground effects, multiple jets, and adjacent surface geometry. In addition, computational methods are discussed including both potential flow based methods, some with empirical and semi-analytical extensions, and Navier-Stokes based computational fluid dynamics (CFD) investigations. Currently modern CFD methods have been able to compute many of the mean flow characteristics of the JICF. Existing CFD methods have not resolved the separated flow region in the near wake of the jet exit. There is also a need for high quality, extensive experimental data which will enable the verification of current and future CFD results and to define unsteady flow characteristics. Author (revised)

The transient features of a supersonic jet exhausting into a low speed cross flow were studied experimentally. The experiments were conducted in the Southampton University's 3.5 m x 2.6 m low speed wind tunnel. Three supersonic jets at ambient temperatures were used, one being a convergent nozzle and the other two being convergent-divergent nozzles having respectively design Mach numbers, M(sub d) = 1.4 and 1.7. Each jet issued in the normal direction to a flat plate mounted at zero incidence in the center of the wind tunnel. The jet pressure ratio varied between 1.2 and 5.0 and the cross flow velocity between 14m/s and 38m/s. Both over-expanded and under-expanded jets were used. The low speed cross flow was found to introduce complex multiple narrow band tones. Changes in the transient flow modes and the levels of the tones were observed from time resolved pressure measurements at various positions on the flat plate. Author (revised)

UNSTEADY WAKE STRUCTURES IN TRANSVERSE JETS

R. M. Kelso, C. Delo (Princeton Univ., NJ.), and A. J. Smits (Princeton Univ., NJ.) *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 8 p Sponsored in part by Fannie and John Hertz Foundation and NSF (For primary document see N94-28003 07-34)

Copyright Avail: CASI HC A02/MF A04

The unsteady vortex structures in the wake of a transverse jet were studied using a new laser scanning apparatus to obtain three-dimensional images of fluorescent dyes in a water channel flow. By scanning the laser at high repetition rates and by using a high-speed video camera to record the images, the three-dimensional, time-evolving concentration field in the wake can be obtained and later reconstructed. Using this system, the separation and roll-up of the flat plate boundary layer and the subsequent convection of that vorticity away from the wall can be visualized. The relationship between the separation and roll-up on the other side of the wake can also be studied. On the basis of the reconstructed concentration fields, an attempt is made to describe the mechanisms of wake vortex formation and explain the results of some previous authors. Author

SEPARATED FLOW GENERATED BY A VECTORED JET IN A CROSSFLOW

A. Krothapalli and C. Shih *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 7 p Sponsored by NASA. Ames Research Center Prepared in cooperation with Florida State Univ., Tallahassee (For primary document see N94-28003 07-34)

Copyright Avail: CASI HC A02/MF A04

Results of an experimental investigation to determine the characteristics of the separated flow region generated by a subsonic vectored rectangular jet in a subsonic crossflow is presented. Using surface visualization techniques, it was found that the upstream separated flow consist of horseshoe vortices that are formed periodically with a frequency corresponding to that of the vortex shedding behind the jet. The size of the recirculation region around the jet is found to decrease with increasing jet vector angle. The variation of the mean primary separation distance upstream of the jet, with velocity ratio revealed the existence of two different flow regimes. The change from one to the other depends on the velocity ratio and the jet vector angle. It is shown that the Strouhal number, based on the vortex shedding frequency and a combination of jet exit and freestream velocities, varies uniquely with velocity ratio. Author

SCALAR MIXING IN THE SUBSONIC JET IN CROSSFLOW

S. H. Smith, A. Lozano, M. G. Mungal, and R. K. Hanson *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 13 p Sponsored by AFOSR (For primary document see N94-28003 07-34)

Copyright Avail: CASI HC A03/MF A04

Results are presented on the structure and mixing of subsonic jets in crossflow. These results are obtained by using planar laser-induced fluorescence of acetone vapor which is carried as a marker of the jet fluid. In addition to providing instantaneous realizations of the jet structure, the data is quantitative in providing instantaneous measures of the jet mixture fraction. Jet to crossflow velocity ratios ranging from 6 to 14, corresponding to momentum ratios of 36 to 196 were examined. It is found that the instantaneous structure is quite complex, dominated by large-scale motions, and bear little resemblance to ensemble-averaged field. Jet fluid is seen in the wake structure in the curved portion of the jet, even though the amounts are small. Mean and rms concentration fluctuations are presented for select cases. Author (revised)

THE INTERACTION REGION ASSOCIATED WITH TWIN JETS AND A NORMAL CROSSFLOW

N. Toy, E. Savory, S. McCusker, and P. J. Disimile (Cincinnati Univ., OH.) *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 11 p (For primary document see N94-28003 07-34)

Copyright Avail: CASI HC A03/MF A04

An experimental investigation of the interaction between twin jets and a normal crossflow using real-time, quantitative, video image analysis of smoke-seeded jets to yield information concerning overall jet growth rates, the widths of the interface regions, intermittencies, p.d.f.s, and spectra of the interface fluctuations is presented. The cases covered are side-by-side and in-line jets, with a nozzle spacing of 5 nozzle exit diameters and a jet velocity/crossflow velocity ratio of 8, together with the single jet cases. Additional data, in the form of velocity vector distributions from five-hole pressure probe measurements, were obtained for comparison with the intermittency profiles in planes across the jets for the case of side-by-side jets with a nozzle spacing of 5 diameters and a ratio of 6. Finally, a parametric study of the effect on the overall jet penetration of velocity ratio (from 4 to 10), nozzle spacing (from 1 to 5 diameters) and nozzle orientation to the crossflow (from in-line to side-by-side, but with normal injection angle) was carried out using a new digital image processing system. The velocity data for the side-by-side case shows that the deflected jets are dominated by one single vortex pair such that the inner vortex of each jet pair are not evident. The video analysis of the three main configurations, side-by-side, in-line and single jet, shows that in all cases the width of the mixing region at any downstream location is similar in

magnitude to the jet half-width (as defined by the mean interface location). The interface widths are similar for the side-by-side and in-line jets but these are greater than the single jet for the intermittency distributions across the interface regions which will enable correlation between the different jet configurations. The parametric study shows that, for a given jet ratio, the in-line jets (0 deg angle) penetrate further than those set at other angles to the crossflow and that changes of angle between 30 deg and 60 deg have less effect upon the overall penetration. For the in-line case it is the second jet, issuing into the lower static pressure region downstream of the first jet, that penetrates furthest into the crossflow.

EXPERIMENTAL DATA FOR CFD VALIDATION OF IMPINGING JETS IN CROSSFLOW WITH APPLICATION TO ASTOVL FLOW PROBLEMS

P. Behrouzi and J. J. McGuirk *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 11 p Sponsored by British Aerospace Public Ltd. Co. (For primary document see N94-28003 07-34)

Copyright Avail: CASI HC A03/MF A04

An experimental facility, used to gather validation data suitable for testing CFD model predictions of multijet ground impingement flows, is described. Water is used as the working medium and LDV measurements of twin impinging jets are reported, both with and without a cross-flowing stream. Emphasis is placed on the presentation of mean and rms velocity contours in the foundation formation region between the jets. The effect of jet splay angle has also been studied. For zero splay or 10 deg of splay-out, the fountain is observed to develop as an upwash flow spatially separated from the two jet flows (jet spacing at six jet diameters); for 10 deg splay-in, a noticeable fountain/jet interaction is observed. Splay-out reduces the strength of the fountain by around 50 percent whereas splay-in has an opposite, strengthening effect for the seven jet diameter impingement height studied here. The effect of a cross-flow (jet/cross-flow velocity ratio of 10) leads to a clear downwind shift of the fountain origin and inclination of the fountain rise. The results presented offer a sufficiently comprehensive mapping of the mean velocity and turbulence fields to form suitable test cases for the validation of CFD models for ground effect flows.

EXPERIMENTAL INVESTIGATION OF THE INTERACTION OF A THRUST REVERSER JET WITH AN EXTERNAL SUBSONIC FLOW

J.-M. Charbonnier, K. Deckers, and G. Wens *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 10 p (For primary document see N94-28003 07-34)

Copyright Avail: CASI HC A02/MF A04

An experimental modelization of a door-type thrust reverser is conducted in a subsonic wind tunnel. The geometry of the model is defined in order to simulate both the internal and external flow of a real thrust reverser. Different door configurations are studied for a selected value of the mass flux injection ratio of three. Visualizations illustrate qualitatively the jet interaction, and extensive mean velocity and pressure measurements are conducted in sections perpendicular to the upstream flow direction with a five hole probe. The total pressure losses and the drag force produced by the thrust reverser are deduced from the measurements. As a result, it shows that the smaller opening angle of the door (56 deg), with a becquet deflection of 15 deg gives the larger drag force. In addition to the classical pair of counter rotating vortices observed in jet in cross flow interactions, a second pair of counter rotating vortices below the main pair is found. The vorticity field is described with good agreement by a simple vortex model simulating the two pairs of vortices. Author (revised)

VECTORED JETS-INDUCED INTERFERENCE ON AIRCRAFT, PREDICTION AND VERIFICATION

R. K. Nangia *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 14 p Sponsored by Defence Research Agency (For primary document see N94-28003 07-34)

Copyright Avail: CASI HC A03/MF A04

The prediction of vectored jet-induced effects on V/STOL configurations during transition phase and maneuvers constitutes an important aspect in the understanding, design, control, and operation of such aircraft. In this paper, a semiempirical modelling of the jet is used within the framework of subsonic singularity methods. Comparisons with experimental data on a wing-body configuration have been presented. In general, acceptable agreement has been demonstrated. Overall, the emphasis has been on predicting jet interference effects on practical configurations with multijet effects and forward and aft nozzles. Configuration effects include tails which operate in a much stronger jet downwash than the wing. Optimization studies can be enabled prior to experimental programs. This process will allow the design cycle to commence with a good idea of the relative effectiveness of the various controls and the changes needed in the flight control system to cope with partially jet-borne phases of flight. Therefore there is a significant potential for encouraging cost and time savings. Areas for further work and improvements of the model have been proposed. It is believed that these aspects will have a constructive impact on current and future practical VSTOL and ASTOVL developments. Author (revised)

NUMERICAL INVESTIGATION OF THRUST VECTORING BY INJECTION OF SECONDARY AIR INTO NOZZLE FLOWS

T. Berens *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 15 p Sponsored by DGLR (For primary document see N94-28003 07-34)

Copyright Avail: CASI HC A03/MF A04

Injection of secondary air into nozzle flows is an efficient method to control the thrust vector angle of an aircraft. A numerical investigation of thrust vectoring has been carried out for hypersonic aircraft in the transonic flight regime. In this speed range, single duct asymmetrical single expansion ramp nozzles operate far off design due to large nozzle exit areas required for optimal thrust coefficients at hypersonic cruise Mach numbers, thus producing large thrust components in the downward direction. Injecting secondary air into the nozzle flow in the critical transonic flight Mach number regime can lead to favorable gross thrust vector angles and thus improved thrust efficiency in flight direction. For a hypersonic aircraft's rectangular convergent-divergent nozzle configuration with a single expansion ramp, two dimensional Euler calculations of the complete afterbody flow field were carried out in the transonic flight regime, investigating subsonic as well as supersonic injection of the aircraft's forebody boundary layer air into the nozzle flow. Subsonic flow of the injected air along the expansion ramp produces a favorable pressure distribution on the ramp and results in advantageous thrust vectors with small force components normal to the flight direction and in best thrust efficiency. The interaction between the external flow, the jet plume flow, and the secondary air flow, as well as the behavior of the thrust vector, due to pressure and temperature variations of the injected forebody boundary layer air, are discussed. Also investigated was the impact of the aircraft's angle of attack on the complete nozzle flow field.

Experimental studies of round jets in cross flow have been made using flying hot-wire and flow visualization techniques. The velocity ratio of the flow ranged from about two to six with the Reynolds number up to 6200. The flying hot wire enables time- and phase-averaged measurements to be made in regions of the flow which cannot be measured accurately using stationary wires. These quantitative results together with the complementary flow visualization studies have allowed the mean topological features of the jet in cross flow to be identified using critical point theory. An understanding of these flow features may provide insight into the large-scale mixing processes which occur in the shear layer of the jet.

Experiments were conducted in a laboratory flume to study the interaction of bivalve siphonal jets with the turbulent boundary layer which forms in the benthic region of shallow estuaries. Beds of siphonate bivalves (clams) 1.8 meters long were simulated to study the formation of a phytoplankton-depleted layer (concentration boundary layer) over bivalves. Refiltration of excurrent fluid through incurrent siphons, which represents a decrease in aggregate feeding efficiency, was measured for two test beds with S/d(sub o) = 6 and 16 and siphon pairs oriented perpendicular to the cross flow direction. Results are expressed as a function of the nondimensional distance downstream, x/d(sub o), the velocity ratio, VR=u(sub j)/U(sub infinity), and the nondimensional animal spacing, S/d(sub o). Laser induced fluorescence was used to obtain quantitative concentration profiles in order to describe the evolution of the flow and to identify parameters that describe the jet/boundary layer interaction.

An inclined jet impinging on the ground creates a wall flow that spreads radially from the point of impingement. If a cross-flow is introduced, the upstream component of the wall flow will separate from the ground and create what has been termed the 'ground vortex.' The ground vortex has been shown to have a significant impact on aircraft aerodynamics and is one of the major contributors to hot gas ingestion. The paper discusses a recent study which included a generic wing-body configuration for assessing the impact of the ground vortex on configuration aerodynamics. Wind tunnel tests using fixed ground boards, moving ground belts, and moving model tests are discussed. The emphasis of the data is macroscopic, i.e. forward location of the vortex, effects of ground height, etc. Author (revised)

The phenomenon of Hot Gas Recirculation for vertical landing jet aircraft and the effect of exhaust gas ingestion on aircraft performance is described. Additionally, our experience with experimental modelling of HGR for aircraft configurations and the scaling of the important parameters is presented. The conflict between scaling the buoyancy of the flowfield and correct modelling of the pressure field is explored, and a number of fundamental experiments addressing this problem are related. It is shown that in the region close to the jets and when the aircraft is very close to the ground that there are quite large differences between the two scaling criteria; the near-field region requires full scale pressures for accurate representation. Away from this region, the Nozzle Pressure Ratio does not greatly affect the flowfield. Testing of a generic aircraft model with a number of different configurations shows that once near-field flowpaths have been eliminated the ingestion levels are underpredicted if the flow-field buoyancy is below full scale. Absolute levels of ingestion are not greatly different between the two scaling criteria, particularly with the large scatter in results which is endemic to the phenomenon. However, it is concluded that for practical configurations, i.e., those with low levels of ingestion, scaling of flowfield buoyancy is more correct than scaling of the pressure field. This method of scaling is appropriate for use in achieving a low ingestion configuration. Author (revised)

INFLUENCE OF HEADWIND ON HOT GAS REINGESTION AND CONSIDERATION OF PRESSURE RATIO SCALING c07

A major concern affecting the operation of Advanced Short Take-Off and Vertical Landing (ASTOVL) aircraft close to the ground is ingestion by the aircraft intakes of engine hot exhaust gas. This hot gas reingestion (HGR) can produce loss of engine thrust and erode engine stability margins. A prime source of HGR is the flow occupying the region in the 'near' and 'mid' fields around the aircraft. The 'near-field' flow can be controlled by aircraft-mounted anti-HGR devices but these are likely to be less effective in containing the mid-field flow which is greatly influenced by headwind. Near and mid-field ingestion on Harrier-type configurations has, for many years, been studied by means of model-scale experiments. In most cases in the United Kingdom, the experiments have been set up observing scaling procedures which include consideration of the buoyant action of the hot gas and imply tests at low jet velocities with dynamic head similarity maintained. It can be argued that low velocities may not be appropriate for currently-conceived ASTOVL aircraft employing high pressure-ratio supersonic exhausts, and it may be more appropriate to test at full-scale nozzle pressure ratios. This paper reviews the effects of headwind on HGR for Harrier-type configurations during landing maneuvers with tests carried out both at low jet velocities consistent with buoyancy scaling (NPR(sub F) = 1. 07) and at velocities representative of full-scale nozzle pressure ratios (NPR(sub f) = 2.46). The HGR results are examined in relation to expectations of the forward-flowing gas cloud height and penetration distance for the engine exhaust streams while under the influence of headwinds. The ingestion of engine exhaust gases into an aircraft intake during jet-lift Advanced Short Take-off and Vertical Lift (ASTOVL) aircraft operation close to the ground is an area of considerable concern and has been the subject of much experimental study. The recirculatory flows follow complex paths which are strongly influenced by interference with the ground, aircraft structures, adjacent jet streams, and by the action of an oncoming headwind. The flows are turbulent at a large scale and unsteady with 'streaks' of hot gas entering the intake in a random manner. This Hot Gas Reingestion (HGR) can erode engine stability margins in a region of aircraft operation where reliable engine performance is critical. To ensure engine stability, sophisticated analysis techniques are required to enable prediction of worst-case destabilizing temperature distortion levels for chosen aircraft/engine combination. This paper describes the development and application of statistical analysis techniques designed to examine results of model experiments. These techniques enable quantitative conclusions to be reached as an extension to qualitative examination of trends from observed data. Due to the nature of the flow and distortion parameter, observed HGR data distributions are frequently not normal (Gaussian), and standard statistical techniques cannot be used. Author (revised)

Control jets are used on space vehicles in order to replace or complement mechanical aerodynamic controls at high altitudes. As a matter of fact, the efficiency of mechanical controls decreases drastically with higher rarefaction levels of external flow. Control jets were experimentally investigated in wind-tunnels. The jets interact with external hypersonic rarefied flows. Jet efficiency and associated interaction mechanisms were analyzed for two types of configurations. The first configuration is a delta wing with transverse control jets issuing from sonic nozzles located close to the trailing edge. Tests are performed with an external hypersonic air flow characterized by a Mach number of about 8, a Reynolds number of 11,000, and a rarefaction parameter V = 0.077. The second configuration is a corner flow interacting with a transverse jet issuing from one hypersonic nozzle. This nozzle is inserted in one of the two walls which make up the corner model. Tests are made under external hypersonic nitrogen flows characterized by a Mach number of about 20 and dynamic pressures ranging from 20 Pa to 620 Pa covering rarefaction levels associated with reentry conditions. COMPARISON OF THE INTERACTIONS OF TWO AND THREE DIMENSIONAL TRANSVERSE JETS WITH A HYPERSONIC FREE STREAM c02

H. E. G. Powrie, G. J. Ball, and R. A. East *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 8 p Sponsored by Defence Research Agency (For primary document see N94-28003 07-34)
Copyright Avail: CASI HC A02/MF A04

The interaction between a three dimensional (circular) sonic jet and a Mach 6.69 cross flow on a flat plate has been investigated experimentally. The results are compared with data from a two dimensional (slot) sonic jet in the same flow. In both cases the undisturbed flow on the plate is laminar. Heat transfer and oil flow visualization have been used to identify separation and reattachment within the flow field which, for the case of circular injection, has revealed a number of vortex cells in the region ahead of the jet. For the two dimensional interaction there is only evidence of one vortex pair in this region; however, a complex flow downstream of the slot jet has been observed. The influence of injectant gas type on the two dimensional interaction flow field is limited to a weak molecular weight dependence implied by separation length data. In contrast, for three dimensional injection, jet gas composition is found to have a marked effect on the size of the interaction flow field, as well as influencing surface heat transfer rate in the vicinity of the injector. EXPERIMENTS ON INTERACTION FORCE OF JETS IN HYPERVELOCITY CROSS-FLOW IN A SHOCK TUNNEL c02

K. W. Naumann, H. Ende, G. Mathieu, and A. George *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 12 p (For primary document see N94-28003 07-34)
Copyright Avail: CASI HC A03/MF A04

This paper discusses experiments on side-jet control efficiency in the hypervelocity flow of a shock tunnel. The parameters of the test flow represent the Mach number, Reynolds number, velocity, and density of tropospheric hypervelocity flight. The experiments are carried out with a model, which is equipped with pyrotechnical charges, a settling chamber, laterally blowing jets, and a set of small accelerometers. The pyrotechnically supplied side-jets also are roughly adequate to those used in sound vehicles. Extensive jet gas diagnostics yield the parameters of the gas and the nozzle flow. The accelerometers incorporated in the model allow direct millisecond aerodynamic force measurement. To provide free-flight during the testing time, a fast-acting mounting support releases the model and grips it again when the test flow has passed the model. Using measured acceleration and Pitot pressure histories allows direct straightforward time-dependent evaluation of the aerodynamic coefficients. The procedure is insensitive to disturbances in the starting phase of the flow or moderate flow variations. The results quantify the force, which is produced by interaction of side-jets and ambient flow, and acts on the surface of the model. At the tropospheric hypervelocity conditions of our test, the interaction force on a flat plate substantially increases jet thrust. Moreover, the results quantify the time necessary to establish quasistationary flow for the actual test conditions. Author (revised)

A NUMERICAL INVESTIGATION OF A SUBSONIC JET IN A CROSSFLOW

Stephen H. Chiu (Space Systems/Loral, Palo Alto, CA.), Karlin R. Roth, Richard J. Margason, and Jin Tso (California Polytechnic State Univ., San Luis Obispo.) *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 14 p Original contains color illustrations (For primary document see N94-28003 07-34)
Copyright Avail: CASI HC A03/MF A04

The flowfield induced by a single, subsonic jet exhausting perpendicularly from a flat plate into a subsonic crossflow has been numerically investigated. The test case was chosen to match available experimental data where the jet Mach number was 0.78, and the freestream Mach number was 0.13. Time-averaged solutions were obtained using the thin-layer Navier-Stokes equations and two overlapping grids. The solutions were sensitive to the radial grid clustering near the edge of the jet and to the far-field boundary conditions. Experimental data comparisons were required to determine the most appropriate jet grid and satisfactory boundary conditions. Globally, the solutions converged in about 6000 iterations. The computational results accurately showed the deflected jet and associated contrarotating vortices. The fine clustered grid in the region upstream of the jet exit allowed the horseshoe vortex in the boundary layer near the jet exit to be captured. Most importantly for aircraft applications, the computed plate pressure distributions compared favorably with the experimental data over most of the surface. However, in the wake region immediately downstream of the jet exit, where there is extensive flow separation, some discrepancies with experimental data were observed. Two turbulence models were used in this study: (1) the zero-equation, two layer Baldwin-Lomax turbulence model; and (2) one-equation Baldwin-Barth turbulence model. The turbulence models gave results which generally compared no better with experimental data than the laminar computation results. Author (revised)

CALCULATION OF SINGLE AND MULTIPLE JETS IN CROSS-FLOW WITH AND WITHOUT IMPINGEMENT USING REYNOLDS-STRESS-TRANSPORT CLOSURE

N. Z. Ince and M. A. Leschziner *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 14 p Sponsored in part by British Aerospace Public Ltd. Co. (For primary document see N94-28003 07-34)
Copyright Avail: CASI HC A03/MF A04

A finite-volume algorithm, incorporating a non diffusive quadratic scheme for the approximation of convection and full second-moment (Reynolds-stress-transport) turbulence closure, is applied to a free jet in moderately strong cross-flow and three jet configurations combining impingement with weak cross-flow, one geometry involving a twin-jet and another a triple-jet arrangement. The primary objective is to identify the merits and weaknesses of Reynolds-stress modelling, in contrast to one based on the isotropic eddy-viscosity approach, in the present complex 3D environment. While open questions remain, due principally to uncertainties arising from boundary conditions and insufficient numerical resolution in isolated highly sheared regions the present calculations provide clear indications, in accord with earlier studies in both 2D and 3D flows, of the superiority of the anisotropic closure. It is also demonstrated that a careful treatment of the jet-discharge conditions can be highly influential in respect of predictive realism. Author

The k-epsilon model and a second moment closure have been applied to the calculation of a slighted heated jet issuing into a cross-flow. Two jet to cross-flow velocity ratios were considered. An assessment of the model performance is made difficult by the high turbulence intensities observed in the recirculation region in the lee of the jet and consequent uncertainty in the hot-wire measurements. Overall, the second moment closure gives slightly better agreement but the difference between the results obtained with the two model is not large. For the low velocity ratio, results are extremely sensitive to the boundary conditions prevailing at jet inlet. The predicted mean temperature profiles appear to be more strongly dependent on the predicted velocity fields than on the scalar field closure. Author

Flowfields of two and three dimensional subsonic jets injected into a crossflow were solved by using a three dimensional Navier-Stokes code (LANS3D). Baldwin-Lomax turbulence model and the algebraic curved jet turbulence model of Oh and Schetz were used depending on the location in the flowfield. Application of characteristic boundary conditions based on Riemann invariants were found to be useful for the convergence of solutions. Computations made using flat bottom grids showed local pressure singularities around the jet exit. It was shown that these singularities could be removed by using grids with a cavity for the jet entrance. Grid skewness was a particularly effective parameter on the prediction of surface pressures. Concentrated spanwise blowing over wings is a technique using mainly the secondary (= nonreactive) effects of a jet in crossflow, with the primary intention to generate and/or stabilize and control separated rolled-up leading edge vortex systems. This means an indirect application of a crossflow jet via triggering another crossflow phenomenon, the L.E. vortex. Based on the results of extensive experimental research, the merits and shortcomings of this technique are overviewed concerning aerodynamic performances, and stability and control aspects. The limits of aerodynamics efficiency are established on an empirical/theoretical basis and compared to experimental results. There is found a definite upper and lower boundary. The author's view is given concerning the practical (non-) applicability of this simple technique and the reasons for missing examples in operational aircraft are discussed via comparison to competitive approaches. PNEUMATIC MANAGEMENT OF BLUNTED-FOREBODY FLOW ASYMMETRY FOR HIGH-ANGLE-OF-ATTACK DIRECTIONAL CONTROL c08

Frederick W. Roos, Charles L. Magness, and Daniel V. Brown *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 6 p (For primary document see N94-28003 07-34)
Copyright Avail: CASI HC A02/MF A04

Low-speed experiments have been conducted to explore the effectiveness of combining nose bluntness, which suppresses the tendency toward flowfield asymmetry, and pneumatic flow-separation control, which triggers flow asymmetry, into a system of pneumatic side-force control for a slender forebody shape at high angles of attack (alpha). The basic forebody shape studied, a 20%-blunted, 3.5-caliber tangent ogive, developed no side force over the range 0 less than or = alpha less than or = 60 degrees. Slight blowing through either or two symmetrically positioned orifices at the blunt nose of the forebody produced a degree of flow asymmetry (and a corresponding side force) that depended on jet massflow rate within limits that varied with alpha, the specific jet configuration, and laminar vs. turbulent boundary-layer separation. Forward-blowing jets were found to be generally more effective that nets normal to the forebody surface in producing pneumatic side-force control. Derived from text

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF A DELTA WING WITH TURBULENT LEADING-EDGE JETS c02

K. J. Craig, L. Roberts, D. I. Greenwell (Bath Univ., England.), and N. J. Wood (Bath Univ., England.) *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 13 p (For primary document see N94-28003 07-34)
Copyright Avail: CASI HC A03/MF A04

Control of the separated flow over a delta wing using Tangential Leading-Edge Blowing has been investigated experimentally and computationally. Tangential Leading-Edge Blowing describes the injection of momentum into the cross flow plane of the wing by thin Coanda wall jets located at the point of cross flow separation. The concept is shown to be capable of generating significant asymmetry in the vortical flowfield, and hence a lateral control capability, up to very high angles of attack. The primary effects of jet blowing have been modeled using a Navier-Stokes computation with an algebraic turbulence model. Author

RECENT DEVELOPMENTS IN THE SIMULATION OF STEADY AND TRANSIENT TRANSVERSE JET INTERACTIONS FOR MISSILE, ROTORCRAFT, AND PROPULSIVE APPLICATIONS

S. M. Dash, B. J. York, N. Sinha, R. A. Lee, A. Hosangadi, and D. C. Kenzakowski *In* AGARD, Computational and Experimental Assessment of Jets in Cross Flow Nov. 1993 21 p (For primary document see N94-28003 07-34)
Copyright Avail: CASI HC A03/MF A04

A review of recent activities focused on the simulation of transverse jet interaction problems using advanced time-asymptotic and time-accurate Navier-Stokes methodology is presented. Missile work has involved the simulation of short-duration control jets issued from solid rocket motor nozzles. For the simulation of time-accurate particle-laden flows, a new Eulerian-based upwind/implicit particle-solver was developed and coupled with the gas-phase solver. Rotorcraft work has involved simulating the interaction of the exhaust plumes with the rotor wake and body aerodynamic flow. Hybrid vortex tracking/Navier-stokes methodology has been implemented with gridding of this complex 3D interactive flow being an issue of primary concern. Propulsive work has emphasized turbulence modeling. For scramjet fuel-injection applications, compressible-dissipation extensions to the k-epsilon turbulence model which provided marked improvements in simulating fundamental high-speed shear layers, have proven to work quite well for transverse jet injection. This paper deals with numerical studies made at AEROSPATIALE-MISSILES about aerodynamic interactions due to the use of pyrotechnical lateral force control. Calculations were performed in order to predict lateral jets interactions on two kinds of missiles: subsonic antitank and supersonic antimissile. In the subsonic case, Euler and Navier-Stokes calculations were compared on a missile body test case. Then, Euler code was applied to an antitank missile configuration, and missile spinning effects were assessed. In the supersonic case, jet stagnation temperature and jet species effects were studied on a surface-to-air missile. Author

The flow field about a delta wing equipped with thrust reverse jets in slow speed flight near the ground has been computed. Results include the prediction of the flow about the delta wing at four fixed heights above the ground, and simulated landing, in which the delta wing descends towards the ground. Comparison of computed and experimental lift coefficients indicates that the simulations can capture at least the qualitative trends in lift-loss encountered by thrust-vectoring aircraft operating in ground effect. The STOL and Maneuver Technology Demonstrator (S/MTD) program was structured to investigate, develop and validate through analysis, experiment and flight test, four specific technologies related to providing current and future high performance fighters with both STOL capability and enhanced combat mission performance. The four technologies are: (1) Two-dimensional thrust vectoring and reversing exhaust nozzle, (2) Integrated Flight/Propulsion Control (IFPC) System, (3) Advanced Pilot Vehicle Interface, and (4) Rough/soft field landing gear. In addition to the required technologies, all-moving canard surfaces were also incorporated into the baseline F-15B. As stated previously, the intent of the demonstration program was to validate specific technologies, it was neither a prototype nor an explicit research program. Starting with an existing aircraft, many wind tunnel tests were performed to define the incremental effects of the specific technology items. Thrust reversing was achieved by blocking the nozzle exit area and exhausting the flow through vane packs on top and bottom of the engine. In the Short Landing (SLAND) mode the engines were at full military RPM and all exhaust flow was diverted through final approach with the reverse vanes pointed aft to provide forward thrust. At touchdown, the vanes quickly swing forward to orient the exhaust flow to provide reverse thrust for the rollout. A significant amount of wind tunnel testing was devoted to measuring jet effects at all conditions but definition of jet effects in ground effect received particular emphasis. Reference 1 documented the development of the S/MTD configuration with details on the wind tunnel data and control laws. Data was presented on the jet effects in ground effect that were predicted. Special control logic was defined to mitigate strong nose-up pitching moments as thrust reversing was initiated after touchdown. A special ground-handling mode was also incorporated for the rollout phase. The flight testing produced some surprising results. The object of the present paper is to document that experience. Data will be summarized briefly for completeness. Pertinent flight test experience will be presented, with results of an innovative analysis technique developed by the contractor. Lastly, future requirements will be discussed. Author

The transitional flight characteristics of a geometrically simplified Short Take-Off Vertical Landing (STOVL) aircraft configuration were measured in the NASA Ames 7- by 10-Foot Wind Tunnel. The experiment was designed to provide detailed data for evaluating the capability of computational fluid dynamics methods to predict the important powered lift flow parameters. The model consists of a 60 deg cropped delta wing planform; a blended fuselage; and tandem, circular, high pressure air jets that exit perpendicular to the flat lower surface. Freestream Mach number is limited to a maximum 0.2. Model angle of attack ranges from -10 deg to +20 deg. The nozzle pressure ratios of both jets are varied between 1 and 3, and the jet exit temperatures are maintained at near ambient conditions. Detailed surface pressure measurements show that suction pressure peaks located on the upper surface of the wing during conventional wingborne flight for angles of attack greater than 5 deg move to the wing lower surface at angles of attack less than 0 deg. A reduction in these suction pressure peaks is observed when the lift jets are operating. With sonic jet exit conditions, a freestream Mach number of 0.14, and 0 deg angle of attack, the jet-induced suckdown is equivalent to a 3.7 deg reduction in angle of attack. Schlieren, laser light sheet flow visualization and total pressure measurements in the jet plumes provide a description of the three-dimensional jet efflux flowfield. Author

At present there is limited information available on effects of free-stream turbulence intensities and scale on both the time average and instantaneous development of a jet in a cross flow. The aim of this study was to investigate such effects on both entrainment and mean path of the jet using primarily experimental methods. The experimental part consisted of measurements using hot wire anemometers, thermocouples and a nine hole vortex probe as well as observations with a color Schlieren system on a jet issuing from a circular aperture in a flat plate. The jet Reynolds numbers of the tests were in the region 2x10(exp 4) to 8x10(exp 4) and the flow could be considered as incompressible for all cases tested. The use of both visualization technique as well as quantitative measurements have proven to be helpful in the description of free-stream turbulence effects. Although it should be noted that some quantitative data can be inferred from the Schlieren observations. The results show that there are clear effects due to variations in free-stream turbulence on the development of the jet. The effects within the range of variation in free-stream turbulence intensity and length scale of the investigation are manifest in terms of all main jet characteristics. These characteristics are the rate of entrainment, the mean jet path and the strength of the main jet vortices. The observed effects are significant, but at present there are no direct trends in the results with increasing or decreasing turbulence scales or intensity to help propose the primary mechanisms involved in the effects. This is the subject of further investigations at the present time. Author

Film-cooling air ejection affects the aerodynamics of turbine blades by the mixing of the coolant with the mainstream as well as by the interaction between the jet and the boundary layer. In the present paper, these effects are studied experimentally and numerically. The results show that the flow in the coolant channel is strongly affected by the main flow around the blade, leading to significant deflection of the coolant air jets. To account for these interactions between the cooling jet and the main flow in the numerical predictions, a multi-block technique is applied. With this technique very complex but structured geometries can be modelled by simply attaching grids of the different sub-domains. For the present investigations, these sub-domains are the two coolant channels at the leading edge and the main flow around the blade. For adaption to the curved geometry of such a turbine blade, a non-orthogonal body fitted grid is used for solving the time average two- or three-dimensional compressible Navier-Stokes equations by a finite volume method. The turbulence is taken into account by the standard k-epsilon model. For discretization of the convective terms the Monotonized-Linear-Upwind scheme (MLU) is used. The pressure-velocity coupling is achieved by the SIMPLEC-algorithm for compressible flows. The calculated results are compared with experimental investigation performed with a L2F-system at a large scaled turbine blade. Three typical blowing ratios are presented. Due to the simultaneous calculation of the coolant flow and the main flow, good agreement was obtained. Author

Flowfield of a subsonic swirling jet injected into a subsonic crossflow was computed by using a three dimensional Navier-Stokes code (LANS3D). Baldwin-Lomax turbulence model and the algebraic curved jet turbulence model of Oh and Schetz were used depending on the location in the flowfield. Characteristic boundary conditions based on Riemann invariants were utilized for the flow in and out planes. A single block grid with a cavity at the jet entrance was used. Author

This paper presents the techniques implemented as well as a collection of the results obtained during an experimentation leading to the S5 wind tunnel of ONERA in the case of a transverse jet of Mach number equal to 2, strongly heated, emerging in a perpendicular flow of the same Mach number. The flow is qualified by means of a miniature 5 hole probe, by thermocouples and tridirectional laser velocimetry. The effects of the temperature on the average and turbulent properties of the jet are discussed. Clear strioscopies are also presented. They highlight the strongly nonstationary nature of this interaction. Transl. by FLS

Experiments have been performed to assess the effectiveness of air-jet vortex generators as alternative to vanes in suppressing shock-induced separation. It is shown that a single jet inclined to the plane of the surface and skewed to the direction of the undisturbed stream produces a single strong vortex and can therefore be treated as the equivalent of a single vane. It follows that jets can be installed in arrays to correspond to arrays of vane vortex generators. A spanwise array of jets is shown to produce closely similar results to an array of co-rotating vane vortex generators of the type that has now been used in very many applications to suppress the effects of shock-induced separation. Air-jet vortex generators should therefore be equally effective in practice and may have significant inherent advantages for many applications. The vortex generators were effective for shock upstream Mach numbers up to and beyond 1.6. The maximum effectiveness occurred close to the generators but they remained reasonably effective for a range of shock positions of up to 50% chord. Some initial pointers are given on the influence of certain design parameters and on what considerations would apply in tailoring the jets to specific applications. Author

CONDENSATION INSIDE TUBES: COMPUTER PROGRAM FOR PRESSURE DROP IN STRAIGHT TUBES (HORIZONTAL AND VERTICAL WITH DOWNFLOW)

Dec. 1993 16 p

(ISSN 0141-402X)

(ESDU-93014; ISBN-0-85679-865-5) Avail: ESDU

ESDU 93014 introduces a Fortran program that implements the calculation procedures of ESDU 90024 and 91023 respectively for vertical and horizontal cases. Those documents should be consulted for details of the empirical correlation used. Since vapor density is an important variable in the calculation and is usually available as a function of saturation temperature, the relationship between pressure and saturation temperature is required at points along the tube, although a constant value of vapor density may be used if the user wishes. The program provides options to use an Antoine or Wagner equation, or to provide a set of values of saturation pressure and temperature; for the vapor density the options are to use the ideal gas law, to provide a set of values of saturation temperature and density or to use a specific correlation equation (log density as a fraction of critical as a five term polynomial function of reciprocal reduced temperature minus one). For a wide range of pure compounds the ESDU Physical Data, Chemical Engineering Sub-series provides values of the constants in the correlation equations for saturation temperature and vapor density. The program (ESDUpac A9314) is provided on disc (uncompiled) in the software volume, and also compiled within ESDUview, a user-friendly shell running under MS DOS that prompts on screen for the input data. A worked example illustrates the use of the program and the formats of the input data and the output. ESDU

VORTEX GENERATORS FOR CONTROL OF SHOCK-INDUCED SEPARATION. PART 1: INTRODUCTION AND AERODYNAMICS

Dec. 1993 63 p

(ISSN 0141-4356)

(ESDU-93024-Pt-1; ISBN-0-85679-877-0) Avail: ESDU

ESDU 93024 summarizes situations where vortex generators have been used to control shock-induced separation. It is suggested that their use should be considered at the design stage and not only as a fix for undesirable characteristics found post-flight. Types of vortex generators are reviewed and the aerodynamic principles of their operation considered. Attention is focused on vane types: co- or counter-rotating and biplane. By applying simplifying assumptions, the degree and range of mixing effectiveness, and the rate of vortex decay, are studied and offer some guidance on the streamwise extent of control, the lateral spacing and the height above the surface that are appropriate for both co- and counter-rotating types. The degree of control achievable on aerofoils is considered, and calculations also show the possible adverse effects on drag. The use of multiple arrays and the use of vortex generators to control shock-induced separation in corners are briefly discussed. The use of wind-tunnel tests to assess the effects of vortex generators is considered. ESDU

VORTEX GENERATORS FOR CONTROL OF SHOCK-INDUCED SEPARATION. PART 3: EXAMPLES OF APPLICATIONS OF VORTEX GENERATORS TO AIRCRAFT

Dec. 1993 35 p
(ISSN 0141-4356)
(ESDU-93026-Pt-3; ISBN-0-85679-879-7) Avail: ESDU

ESDU 93026 illustrates by case studies the use of the information in Parts 1 and 2 on the use of vortex generators to control shock-induced separation. The examples are the control of internal noise by the application of vortex generators on the forward cabin roof of a business aircraft (Gulfstream III), the control of separation associated with a three-shock pattern near the tip of a highly swept and tapered model wing in a wind-tunnel, and the improvement of the buffet maneuver boundary on a straight wing interceptor aircraft of the fifties. In each case the geometric details of the arrays of vortex generators tested are provided, the results obtained are described, and the aerodynamic principles involved that influence those results are assessed. A PARALLEL MULTIGRID ALGORITHM FOR SOLVING THE NAVIER-STOKES EQUATIONS ON A TRANSPUTER SYSTEM

Friedhelm Schieweck (Technical Univ. of Magdeburg, Germany.) 4 Nov. 1992 39 p Sponsored by DFG Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Preprint-699; ETN-94-95085) Avail: CASI HC A03

The numerical solution of the stationary incompressible Navier-Stokes equations for a wide range of Reynolds numbers is considered. A nonconforming finite element discretization of upwind type is used. For solving the discrete systems of equations within an outer nonlinear iteration, a robust multigrid algorithm, which admits a slightly modified parallel version with nearly the same good properties, is proposed. The parallel efficiency for an implementation on a transputer system, when changing the number of employed processors and the number of used grid levels, is studied. ESA

FORCED CONVECTION HEAT TRANSFER IN STRAIGHT TUBES. PART 2: LAMINAR AND TRANSITIONAL FLOW

Aug. 1993 27 p Supersedes ESDU-68006
(ISSN 0141-402X)
(ESDU-93018-Pt-2; ESDU-68006; ISBN-0-85679-870-3) Avail: ESDU

ESDU 93018 presents Nusselt number data in laminar flow for conditions of either uniform wall temperature or uniform heat flux in fully-developed flow, flow that is thermally-developing (where the heated section is preceded by an isothermal length exceeding the hydrodynamic entry length), and flow that is developing simultaneously both thermally and hydrodynamically. The effect of variable fluid properties is considered and a correction for radial viscosity variation in liquids is recommended, but no correction is felt necessary for gases, following an assessment of the available data. For mixed convection conditions only a uniform wall temperature condition is considered. Nusselt number data are given for buoyancy-assisted flow in vertical tubes (heated upflow and cooled downflow) and for buoyancy-opposed flow. Data are also provided for flow in horizontal tubes. The ranges of conditions for which the recommended correlations have been tested are tabulated for the mixed convection conditions. For transitional flow an interpolation function in Nusselt number is suggested to be used between the limiting values in laminar and turbulent flow at Reynolds numbers (based on tube diameter) of 2000 and 8000, respectively. Worked examples illustrate the use of the equations and methods. ESDU 92003 provides guidance on the boundaries between the flow regimes. ESDU

ACOUSTIC BUBBLE SIZING, USING ACTIVE AND PASSIVE TECHNIQUES TO COMPARE AMBIENT AND ENTRAINED POPULATIONS

A. D. Phelps, T. G. Leighton, M. F. Schneider, and P. R. White Mar. 1994 11 p
(ISVR-TR-229) Copyright Avail: Issuing Activity (Inst. of Sound and Vibration Research, Univ. of Southampton, Southampton SO9 5NH, England)

Details of the progress into sizing bubbles actively by means of the two frequency insonation method are included and the success of examining the subharmonic sum-and-difference coupling is outlined. In addition, preliminary results are presented which relate to investigations into the variation of the subharmonic response with differing excitation amplitude and step size between successive interrogating signals, and examinations into the reproducibility of the response. Work was also done on the passive sizing of bubbles upon entrainment with the Gabor transform technique, which gives a fast and accurate representation of the bubble's resonant frequency, of the time at which entrainment occurs and of the amplitude of the signal. A MODELLING OF THE NOISE FROM SIMPLE COAXIAL JETS. PART 3: WITH HOT PRIMARY FLOW

M. J. Fisher and G. A. Preston Jan. 1994 42 p
(ISVR-TR-230-Pt-3) Copyright Avail: Issuing Activity (Inst. of Sound and Vibration Research, Univ. of Southampton, Southampton SO9 5NH, England)

The third part of a continuing study of the noise of coaxial jets is described and modifications to the model developed previously to allow for the effect of heated flow from the primary nozzle are described. The essential feature of the model developed for the prediction of the noise from isothermal coaxial jets was the identification of three flow regions whose noise production could be obtained from single stream jet prediction methods. In particular it was shown that noise from the principal interaction zone could be calculated using single jet prediction methods as long as account was taken of the fact that measured turbulence levels in this region were lower than those observed in a single isolated jet at the same center-line velocity. For isothermal flows, within which only quadruple sources exist, allowance for the reduced turbulence is straightforward. However for heated flows both dipole and quadruple sources exist which have different dependencies on turbulence level. Hence to predict the noise one needs to know the relative contributions of the dipole and quadruple sources. Use was made of previously published results for these relative contributions, as a function of velocity and temperature, for single jets. This then permits prediction of the noise from the interaction zone which is subsequently combined with that from the secondary jet and the fully mixed flow region, as before. Comparison between data and prediction over a range of angles of observation, velocities and temperatures shows a very acceptable level of agreement. Author (revised)

ON THE USE OF FEEDBACK TO CONTROL SOUND RADIATION FROM A PLATE EXCITED BY A TURBULENT BOUNDARY LAYER

D. R. Thomas and P. A. Nelson Jan. 1994 60 p
(ISVR-TR-227) Copyright Avail: Issuing Activity (Inst. of Sound and Vibration Research, Univ. of Southampton, Southampton SO9 5NH, England)

It is shown that the problem of applying active control to simply supported plate excited by a turbulent boundary layer can be presented in a form which allows the application of optimal control theory. Linear regulator theory and stochastic linear regulator theory are briefly summarized and the application of the latter to sound radiation from a vibrating structure is illustrated by the simple example of a rigid piston excited by a random force. It is shown that the optimal control theory can be applied to such a problem if the sound power radiated by the structure is estimated from the vibration signal by means of a 'radiation filter'. A modal model for the vibration of an elastic structure is presented and the state space realization of the model is given. It is shown that a simple Corcos model of the turbulent boundary layer excitation can be modeled as a number of 'excitation filters'. The state space realization of these filters can be combined with the state space model of a vibrating plate to give a state space model of a turbulent boundary layer excited plate to which optimal control theory can be applied. In similar fashion the sound power radiated by the plate can be estimated by means of a 'radiation filter matrix'. A detailed account of the calculation of such a 'radiation filter matrix' is given. Hence, the state space forms of the 'excitation filters' and 'radiation filter matrix' can be combined with the state space model of the plate to give a system state space realization which can be used in the solution of a linear quadratic regulator problem. Once in such a form optimal control analysis is applied to the state equations and optimal reductions in the far field radiated power are obtained for various arrangements of control forces. These results give insight into the possibilities for obtaining useful reductions in turbulent boundary layer induced noise in aircraft by the application of feedback control. They do not, however, enable the simple design of practical controllers. Author (revised)

LOCALIZED AND DISTRIBUTED BOUNDARY-LAYER RECEPTIVITY TO CONVECTED UNSTEADY WAKE IN FREE STREAM
Meelan Choudhari Apr. 1994 22 p
(Contract NAS1-19299; RTOP 538-05-15-03)

Receptivity to a model convected disturbance in the presence of localized and distributed variations in wall geometry and wall-suction velocity is examined. The model free-stream disturbance corresponds to the time-harmonic wake of a vibrating ribbon that is placed at a suitable distance above the surface of a thin airfoil. The advantages of using this disturbance for experiments on receptivity to convected disturbances are outlined. A brief parametric study is presented for a flat-plate boundary layer. The study quantifies the effect of wake position as well as wake width; in addition, it should be helpful in the choice of an optimal setting for a controlled experiment of the above type, which the above parametric study shows as feasible. The Drift Scan Camera (DSC) System acquires image data from a CCD camera. The DSC is divided physically into two subsystems which are tightly coupled to each other. Functionality is split between these two subsystems: the front-end performs data acquisition; and the host subsystem performs near real-time data analysis and control. Yet, through the use of backplane-based Remote Procedure Calls, the feel of one coherent system is preserved. Observers can control data acquisition, archiving to tape, and other functions from the host, but, the front-end can accept these same commands and operate independently. The DSC meets the needs for such robustness and cost-effective computing. DOE

DETECTION GEOMETRY AND RECONSTRUCTION ERROR IN MAGNETIC SOURCE IMAGING
Paul Hughett and Thomas F. Budinger Nov. 1993 4 p Presented at the IEEE Medical Imaging Conference, San Francisco, CA, 4-6 Nov. 1993
(Contract DE-AC03-76SF-00098)
(DE94-004012; LBL-34841; CONF-9311114-3) Avail: CASI HC A01/MF A01

A recently developed reconstruction algorithm for magnetic source imaging exploits prior knowledge about source location, source power density, detector geometry, and detector noise power to obtain an explicit estimate of the reconstruction error. This paper demonstrates the application of the new algorithm to the optimal design of practical detector arrays to minimize the reconstruction error in specific applications. For a representative configuration for magnetocardiography, the optimal array width (for minimum reconstruction error) varies from 19 to 28 cm depending on the assumed source depth, number of detectors, source power and noise power. The reconstruction accuracy ranges from 5% of the a priori standard deviation for the sources nearest the detector plane to 95% of the a priori deviation for the deepest sources. The reconstruction error was found to depend on accidental alignments between dipole sources and point detectors, indicating that a more sophisticated model is required for accurate estimates of reconstruction error. The error calculation is fast, taking about a second for this problem on a workstation-class computer. The availability of a method for rapidly computing the reconstruction error for any given source characteristics and detector geometry will facilitate the optimal design of magnetometer array size, element spacing, and orientation for specific applications in biomagnetic and geomagnetic source imaging. (DE93-616664; JINR-R-13-91-380) Avail: CASI HC A03 (US Sales Only)

The response of an electromagnetic calorimeter using wavelength shifting fibers for the readout have been investigated. The calorimeter has been built as a sandwich of lead and scintillator plates. The fibers have been inserted into holes perpendicular to the plates. This calorimeter has been exposed to electrons, hadrons and muons in the energy range between 0.5 and 4.5 GeV, obtaining an average energy resolution of 11.4%/(radical)E for electrons. Two algorithms for reconstruction the central position of an electromagnetic shower have been applied. The better algorithm has given a spatial resolution of 3.9 mm. Also light yield, uniformity of response and (pi)-e separation have been studied. DOE

REAL-TIME 3-D POSE ESTIMATION USING A HIGH-SPEED RANGE SENSOR
David A. Simon, Martial Hebert, and Takeo Kanade Nov. 1993 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273873; CMU-RI-TR-93-24) Avail: CASI HC A03

A system which can perform full 3-D pose estimation of a single arbitrarily shaped, rigid object at rates up to 10Hz is described. A triangular mesh model of the object to be tracked is generated offline using conventional range sensors. Real-time range data of the object is sensed by the CMU high speed VLSI range sensor. Pose estimation is performed by registering the real-time range data to the triangular mesh model using an enhanced implementation of the Iterative Closest Point (ICP) Algorithm introduced by Besl and McKay. The method does not require explicit feature extraction or specification of correspondence. Pose estimation accuracies on the order of 1mm in translation and 1 degree in rotation were measured. DTIC

SURVEY OF VISUALIZATION AND ANALYSIS TOOLS
P. J. Meyer Jan. 1994 38 p
(NASA-TM-108436; NAS 1.15:108436) Avail: CASI HC A03/MF A01

A large number of commercially available visualization and analysis tools are available to the researcher. Some of the strengths and limitations of some of these tools, from the viewpoint of the earth sciences discipline, are discussed. Visualization and analysis tools fall into one of two categories: those that are designed to a specific purpose and are non-extensive and those that are generic visual programming tools that are extensible. Most of the extensible packages examined incorporate a data flow paradigm. Author (revised)

BREAKWIRE TECHNIQUE FOR HYPERVELOCITY MEASUREMENT
Michael Podlesak Sep. 1993 44 p
(AD-A274779; MRL-TR-92-39; DODA-AR-008-223) Avail: CASI HC A03/MF A01

An electrical breakwire technique for measuring the speed of hypervelocity projectiles is described and assessed, using Boomer, a large scale exploding foil flying plate generator. Two techniques were tested, a dual breakwire method and a single breakwire method. The dual breakwire method is the simpler of the two, but it was found to be less reliable than the single breakwire approach. With the single breakwire method, a reasonable approximation to the projectile's velocity-time-history can be obtained by conducting a series of experiments where a range of times of arrival of the flyer is measured as a function of the breakwire position only. However, accuracy of this technique depends on shot-to-shot consistency and the velocity versus time resolution is limited by the number of different positions of the projectile's trajectory at which the firings can be performed. Compared with other velocity measurement techniques, the breakwire method was found reasonably consistent and effective, in terms of simplicity, turnaround time, low cost and ability to operate within an environment containing high levels of electromagnetic noise in the radio-frequency and optical spectrum. Analysis of the breakwire data from Boomer experiments has indicated a possibility of improvement in the accuracy of the single breakwire technique through correlation of the time-of-break with variations in the Boomer-current waveform. Energy and coordinate resolutions of unsegmented layered uranium calorimeters with the scintillator with cross sections of 40 x 20 cm and 15 x 15 cm have been determined. The obtained experimental data are compared with the results of the calorimeter simulation using the GEANT3.13 program. The obtained results are in a good agreement with the analytical predictions both for the calorimeter with the 0.5 cm uranium plate and that with a 0.2 cm uranium plate. The conclusion is made on a possibility to use those type calorimeters in physical experiments. DOE

ON THE APPLICATION OF ALLAN VARIANCE METHOD FOR RING LASER GYRO PERFORMANCE CHARACTERIZATION
L. C. Ng 15 Oct. 1993 29 p
(Contract W-7405-eng-48)
(DE94-003880; UCRL-ID-115695) Avail: CASI HC A03/MF A01

The method of Allan variance and its application to the characterization of a Ring Laser Gyro's (RLG) performance is described. Allan variance, a time domain analysis technique, is an accepted IEEE standard for gyro specifications. The method was initially developed by David Allan of the National Bureau of Standards to quantify the error statistics of a Cesium beam frequency standard employed as the U.S. Frequency Standards in the 1960's. The method can, in general, be applied to analyze the error characteristics of any precision measurement instrument. The key attribute of the method is that it allows for a finer, easier characterization and identification of error sources and their contribution to the overall noise statistics. An overview of the method is presented, the relationship between Allan variance and power spectral density distribution of underlying noise sources is explained, the batch and recursive implementation approaches are described, the Allan variance computation is validated with a simulation model, and the Allan variance method is illustrated using data collected from several Honeywell LIMU units. ATTACHMENT TECHNIQUES FOR HIGH TEMPERATURE STRAIN Final Report, Nov. 1990 - Jan. 1993
Steve P. Wnuk, Jr. Jan. 1993 147 p
(Contract F33615-90-C-3215)
(AD-A274766; WL-TR-93-3020) Avail: CASI HC A07/MF A02

Attachment methods for making resistive strain measurements to 2500 F were studied. A survey of available strain gages and attachment techniques was made, and the results are compiled for metal and carbon composite test materials. A theoretical analysis of strain transfer into a bonded strain gage was made, and the important physical parameters of the strain transfer medium, the ceramic matrix, were identified. A pull tester to measure pull-out tests on commonly used strain gage cements indicated that all cements tested displayed adequate strength for good strain transfer. Rokide flame sprayed coatings produced significantly stronger bonds than ceramic cements. An in-depth study of the flame spray process produced simplified installation procedures which also resulted in greater reliability and durability. Application procedures incorporating improvements made during this program are appended to the report. Strain gages installed on carbon composites, Rene' 41, 316 stainless steel, and TZM using attachment techniques developed during this program were successfully tested to 2500 F. Photographs of installation techniques, test procedures, and graphs of the test data are included in this report. DTIC

THE RESPONSE OF AN HYPERPURE Ge DETECTOR TO IONIZING RADIATION Ph.D. Thesis
Shaoying Tong Jul. 1993 172 p
(ISBN-0-315-83968-6; CTN-94-61044) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The detailed response of a hyperpure Ge detector to ionizing radiation was studied with regard to the radiation ionization energy ratio Ei/E0, using radioactive alpha and gamma sources and accelerated ion beams. Effects of temperature and bias voltage variation were investigated. The response to charged particles and gamma rays was measured simultaneously by using 152Eu, 60Co, and 137Cs gamma ray sources. Contrary to earlier conclusions, a difference of about 1 percent between E0 and E(alpha or proton) was found in Ge, often showing results qualitatively in accord with the observed behavior for Si semiconductor detectors. The functional behavior of E(alpha)/E0 and E(proton)/E0 exhibits a nonlinear response of the Ge detector as a function of ion energy for a given projectile, similar to the results observed for Si detectors. The energy loss in the window of the Ge detector is found to vary with the energy of the incident particle in a manner that does not agree with the stopping power curve. Pronounced channeling effects are evident in the pulse height spectra as the incidence angle of the ions is rotated with respect to the detector surface normal. Monte Carlo calculations of the projectile energy loss under channeling conditions are in qualitative agreement with experimental observations. Author (CISTI)

EVALUATION OF THE PROTOTYPE DUAL-AXIS WALL ATTITUDE MEASUREMENT SENSOR
Douglas T. Wong Feb. 1994 46 p
(RTOP 505-59-54-02)
(NASA-TM-109056; NAS 1.15:109056) Avail: CASI HC A03/MF A01

A prototype dual-axis electrolytic tilt sensor package for angular position measurements was built and evaluated in a laboratory environment. The objective was to investigate the use of this package for making wind tunnel wall attitude measurements for the National Transonic Facility (NTF) at NASA Langley Research Center (LaRC). The instrumentation may replace an existing, more costly, and less rugged servo accelerometer package (angle-of-attack package) currently in use. The dual-axis electrolytic tilt sensor package contains two commercial electrolytic tilt sensors thermally insulated with NTF foam, all housed within a stainless steel package. The package is actively heated and maintained at 160 F using foil heating elements. The laboratory evaluation consisted of a series of tests to characterize the linearity, repeatability, cross-axis interaction, lead wire effect, step response, thermal time constant, and rectification errors. Tests revealed that the total RMS errors for the x-axis sensor is 0.084 degree, and 0.182 degree for the y-axis sensor. The RMS errors are greater than the 0.01 degree specification required for NTF wall attitude measurements. It is therefore not a viable replacement for the angle-of-attack package in the NTF application. However, with some physical modifications, it can be used as an inexpensive 5-degree range dual-axis inclinometer with overall accuracy approaching 0.01 degree under less harsh environments. Also, the data obtained from the tests can be valuable for wind tunnel applications of most types of electrolytic tilt sensors. Author (revised)

DESIGN OF A HIGH-PRECISION DOUBLE CRYSTAL TUNABLE MONOCHROMATOR
M. Shleifer, S. Sharma, M. Woodle, E. Rotela, and C. Brite 1993 4 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers (SPIE), San Diego, CA, 11-16 Jul. 1993
(Contract DE-AC02-76CH-00016)
(DE94-003004; BNL-49661; CONF-930722-52) Avail: CASI HC A01/MF A01

This paper describes a UHV-compatible double crystal monochromator with independent drives for 2 linear and 2 angular crystal motions. Precise angular crystal positioning is achieved by using a spindle with a double gimbal mechanism which converts linear motion of 0.1 micron to an angular motion of 0.042 arcsec. In order to decrease thermal distortions the crystal intercepting white beam is watercooled. DOE

SP INDUSTRY CALORIMETER FOR RATE OF HEAT RELEASE MEASUREMENTS UP TO 10MW
Martin Dahlberg 1993 23 p
(PB94-124211; SP-RAPP-1992:43; ISBN-91-7848-361-1) Avail: CASI HC A03/MF A01

The Swedish National Testing and Research Institute (SP) has installed a 10 MW fire calorimeter for rate of heat release measurements, similar to the one at Factory Mutual Research Corporation (FMRC). It can be used to classify commodities with respect to their fire hazard, to evaluate the efficiency of sprinkler systems, for chemical analysis of the combustion gases from hazardous fires, to produce input data for the fire modelling, etc. A large hood collects the fire gases and leads them into a duct where gas velocity, gas temperature, smoke density, and contents of oxygen, carbon dioxide, and carbon monoxide are measured. On the basis of these measurements, mass flow and rate of heat release are calculated. The rate of heat release is calculated according to the oxygen consumption principle. The upper limit for measurements is approximately 10 MW and the lower is 0.1 MW. NTIS

CALIBRATING/TESTING METERS IN HOT WATER TEST BENCH VM7 [KALIBRERING/PROVNING AV MAETARE I UTRUSTNING VARM-VATTENBAENK VM7]
E. Kling, K. Stolt, P. Lau, and K. Mattiasson 1993 44 p In SWEDISH
(PB94-124294; SP-RAPP-1993:26) Avail: Issuing Activity (National Technical Information Service (NTIS))

A Hot Water Test Bench, VM7, has been developed and constructed for the calibration and testing of volume and flowmeters, in a project at the National Volume Measurement Laboratory at the Swedish National Testing and Research Institute. The intended area of use includes use as a reference at audit measurements, e.g. for accredited laboratories, calibration of meters for the industry and for the testing of hot water meters. The objective of the project, which was initiated in 1989, was to design equipment with stable flow and with a minimal temperature drop even at very low flow rates. The principle of the design is a closed system with two pressure tanks at different pressures. The water is led from the high pressure tank through the test object and the volume standard, in the form of master meters or a piston prover alternatively, to the low pressure tank. Calibrations/tests are made comparing the indication of the test object to that of master meters covering the current flow rate. These are, in the same test cycle, calibrated to the piston prover. Alternatively, the test object can be calibrated directly to the piston prover. NTIS

HIGH TEMPERATURE SENSOR/MICROPHONE DEVELOPMENT FOR ACTIVE NOISE CONTROL Final Technical Report, 1 Dec. 1990 - 30 Nov. 1993
Thomas R. Shrout 1993 165 p
(Grant NAG3-1225)
(NASA-CR-195214; NAS 1.26:195214) Avail: CASI HC A08/MF A02

The industrial and scientific communities have shown genuine interest in electronic systems which can operate at high temperatures, among which are sensors to monitor noise, vibration, and acoustic emissions. Acoustic sensing can be accomplished by a wide variety of commercially available devices, including: simple piezoelectric sensors, accelerometers, strain gauges, proximity sensors, and fiber optics. Of the several sensing mechanisms investigated, piezoelectrics were found to be the most prevalent, because of their simplicity of design and application and, because of their high sensitivity over broad ranges of frequencies and temperature. Numerous piezoelectric materials are used in acoustic sensors today; but maximum use temperatures are imposed by their transition temperatures (T(sub c)) and by their resistivity. Lithium niobate, in single crystal form, has the highest operating temperature of any commercially available material, 650 C; but that is not high enough for future requirements. Only two piezoelectric materials show potential for use at 1000 C; AlN thin film reported to be piezoactive at 1150 C, and perovskite layer structure (PLS) materials, which possess among the highest T(sub c) (greater than 1500 C) reported for ferroelectrics. A ceramic PLS composition was chosen. The solid solution composition, 80% strontium niobate (SN) and 20% strontium tantalate (STa), with a T(sub c) approximately 1160 C, was hot forged, a process which concurrently sinters and renders the plate-like grains into a highly oriented configuration to enhance piezo properties. Poled samples of this composition showed coupling (k33) approximately 6 and piezoelectric strain constant (d33) approximately 3. Piezoactivity was seen at 1125 C, the highest temperature measurement reported for a ferroelectric ceramic. The high temperature piezoelectric responses of this, and similar PLS materials, opens the possibility of their use in electronic devices operating at temperatures up to 1000 C. Concurrent with the materials study was an effort to define issues involved in the development of a microphone capable of operation at temperatures up to 1000 C; important since microphones capable of operation above 260 C are not generally available. The distinguishing feature of a microphone is its diaphragm which receives sound from the atmosphere: whereas, most other acoustic sensors receive sound through the solid structure on which they are installed. In order to gain an understanding of the potential problems involved in designing and testing a high temperature microphone, a prototype was constructed using a commercially available lithium niobate piezoelectric element in a stainless steel structure. The prototype showed excellent frequency response at room temperature, and responded to acoustic stimulation at 670 C, above which temperature the voltage output rapidly diminished because of decreased resistivity in the element. Samples of the PLS material were also evaluated in a simulated microphone configuration, but their voltage output was found to be a few mV compared to the 10 output of the prototype. ADVANCED TECHNOLOGY DEVELOPMENT MULTI-COLOR HOLOGRAPHY Final Report, 1 Feb. 1993 - 31 Jan. 1994
Chandra S. Vikram 19 Jan. 1994 36 p
(Contract NAS8-38609)
(NASA-CR-193931; NAS 1.26:193931; UAH5-33157) Avail: CASI HC A03/MF A01

Several key aspects of multi-color holography and some non-conventional ways to study the holographic reconstructions are considered. The error analysis of three-color holography is considered in detail with particular example of a typical triglycine sulfate crystal growth situation. For the numerical analysis of the fringe patterns, a new algorithm is introduced with experimental verification using sugar-water solution. The role of the phase difference among component holograms is also critically considered with examples of several two- and three-color situations. The status of experimentation on two-color holography and fabrication of a small breadboard system is also reported. Finally, some successful demonstrations of unconventional ways to study holographic reconstructions are described. These methods are deflectometry and confocal optical processing using some Spacelab III holograms. Author (revised)

THE OPAL VERTEX DETECTOR Ph.D. Thesis
J. Michael Roney Feb. 1989 264 p
(ISBN-0-315-51152-4; CTN-94-60971) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A high resolution charged particle tracking detector has been developed to measure vertex topologies of the subatomic particles produced in e+ e- collisions. The vertex detector is a cylindrical drift chamber segmented radially into an axial and stereo layer, each divided into 36 jet cells. A detector prototype containing four axial and two stereo cells was built to measure various characteristics of the detector design and to determine the limitations of spatial resolution in this design. It was studied using a pion test beam under a variety of operating conditions with two types of chamber gas. The prototype experiments showed that the detector drift time resolutions were limited mainly by chamber pulse nonuniformities. If a gas having a reduced drift velocity is used, the design has a potential for obtaining resolutions better than 30 micrometers. A simple calibration technique that preserved most of the intrinsic resolution was developed.

Under optimal conditions, the end-to-end difference technique provided a measurement with a resolution of 100 ps, equivalent to a spatial resolution of 2 cm. The OPAL vertex detector was built on the basic prototyped design with some modifications that would optimize the detector for operation with a low drift velocity gas. The results of the prototype studies were verified in early tests with the complete OPAL detector. Author (CISTI)

ACOUSTO-OPTICAL POST-PROCESSOR TIME-INTEGRATING CORRELATOR CALIBRATION UPDATES Final Report
P. Baker 12 Feb. 1992 11 p Limited Reproducibility: More than 20% of this document may be affected by poor print
(DSIS-94-00053; CTN-94-61092) Avail: Issuing Activity

The acousto-optical signal processing facility and time integrating correlator system has been updated to allow proper handling of multiple peaks and to increase the readout rate. These modifications are described. In the supervisor task, a phase shift dialog box has been added to the phase shift menu items. This dialog box allows the operator to limit the area examined while searching for peaks or to specify the peak location directly. An amplitude offset calibration dialog box has been added to the amplitude offset menu item. This dialog box allows the operator to limit the area examined during the amplitude offset calibration, which is designed to perform calculations on a portion of the correlogram that does not contain a peak. In addition, the interface between the photodetector and personal computer has been modified to double the maximum pixel clock rate to 10 MHz. Author (CISTI)

TEST AND EVALUATION OF THE LITTON (CANADA) CANADIAN STRAPDOWN GYROSCOPE (CSG-2) PERFORMANCE EVALUATION UNIT (PEU)
M. F. Vinnins and L. D. Gallop Sep. 1988 43 p
(DREO-1010; DSIS-94-00101; CTN-94-61115) Avail: CASI HC A03/MF A01

A prototype gyroscope used for evaluation purposes in an experimental attitude and heading reference system employs unique fabrication methods including laser welding and advanced electro-discharge machining. The result is a two degree of freedom, tuned rotor gyroscope which is highly stable yet inexpensive, capable of random drift rates of under 0.01 deg/hour. Two gyroscopes were integrated into a performance evaluation unit (PEU) containing three accelerometers in order to verify gyroscope performance in a harsh system environment. Extensive laboratory tests included measurements of drift coefficients, instrument misalignments, temperature sensitivity, and scale factor stability and deviation. System effects on instrument performance were evaluated. Individual gyroscope performance was well within specification although a relatively low torquer scale factor resulted in a predicted large scale factor deviation over the desired rate range due to torquer heating effects. System performance was seriously impaired due to the wheel noise caused by poor filtering and shielding within the package and poor temperature control of the PEU. In addition, since little effort was put into sensor modeling, software error compensation within the PEU is inadequate to demonstrate the instrument performance capabilities in a convincing manner. A prototype miniature and modular multi-channel analyzer (M3CA) has been developed. The prototype brings together hardware and software technologies in an instrument that can be effectively used in many safeguards, arms control, nuclear industry, and environmental applications. The design uses modular building blocks for both hardware and software. It is much easier to interface to external controllers than previous instruments. The prototype instrument demonstrates that low-power instruments now have the capabilities and performance required in many applications where, previously, only mains-powered instruments have been used. This paper will summarize performance results of the prototype with regard to the first application as well as the ultimate performance of such an instrument. Derived from text

FLEXIBLE RANGE FINDING APPLIED TO 3D SURFACE SYNTHESIS: A PSEUDO-TRINOCULAR APPROACH Ph.D. Thesis
Tongminh Hong 1992 219 p
(ISBN-0-315-84616-X; CTN-94-61067) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

An important area in machine vision and computer graphics is surface modeling, which involves the issue of data acquisition. A new range finding system is proposed which exploits perspective invariance (cross ratio), the targeting capability of structural lighting (slide projector), and epipolar planes' geometry (trinocular strategy). The system allows a fully autonomous calibration process and is highly efficient in terms of speed and accuracy. The system eliminates the ambiguity in disparity matching experienced in stereopsis, the extra image processing encountered in the trinocular system, the tedious reorganization of range data into a rectangular domain for surface modeling, and the scanning process of most active range finders that are not suitable for moving objects. Research described includes the development of several new camera calibration techniques, reformulation of the epipolar lines geometry method, and a rigorous study of the orientation constraints of the sensors (cameras and projector) in order to enhance the robustness of the vision system. The superiority of this new pseudo trinocular approach over the active structural lighting method and the passive binocular and/or trinocular techniques is convincing. It is believed that the proposed range finder has considerable potential for surface modeling. Author (CISTI)

Experimental analysis of an oscillation mode 500 kW gyrotron at 120 GHz with a TE12,2 whispering gallery mode is reported. Using a k-spectrometer, the oscillation mode was measured. As a result, the oscillation mode was confirmed to be TE12,2 whispering gallery mode, which coincides with the designed value. Also, it is recognized the gyrotron is operated at TE9,3 or TE6,4 mode by adjusting the axial magnetic field. In addition to the major mode, some spurious modes were observed.

These modes are considered to be caused by a mode conversion from the main mode in the transmission line between the gyrotron cavity and the k-spectrometer. DOE

DEVELOPMENT OF A HOLOGRAPHIC ILLUMINATION SYSTEM FOR A TIME-INTEGRATING CORRELATOR Final Report
Mar. 1992 11 p
(DSIS-94-00111; CTN-94-61124) Avail: CASI HC A03/MF A01

Work was performed to design and fabricate a special type of diffraction grating called a Dammann grating to be used as a precision beamsplitter for the illumination of a time integrating correlator. Dammann gratings are a type of binary phase computer generated hologram with a periodic fringe structure. The gratings had to show a very precise diffraction behavior. The reconstruction (or zero order) beam had to be almost eliminated while the first orders were maximized. The three steps in producing the grating include design of the diffractive structure, recording of the diffractive structure by E-beam, and recording of the Dammann gratings by microlithographic techniques. The optical performance of the Dammann gratings is compared to specifications, showing that the gratings are either very close to the required specifications or surpass them. Author (CISTI)

The present authors have been seeking for some time to improve the resolution of holographic microscopy and have engaged in a continuing series of experiments using the X1A soft x-ray undulator beam line at Brookhaven. The principle strategy for pushing the resolution lower in these experiments has been the use of polymer resists as x-ray detectors and the primary goal has been to develop the technique to become useful for examining wet biological material. The authors report on progress in the use of resist for high-spatial-resolution x-ray detection. This is the key step in in-line holography and the one which sets the ultimate limit to the image resolution. The actual recording has always been quite easy, given a high-brightness undulator source, but the difficult step was the readout of the recorded pattern. The authors describe how they have built a special instrument: an atomic force microscope (AFM) to read holograms recorded in resist. They report the technical reasons for building, rather than buying, such an instrument and they give details of the design and performance of the device. The authors also describe the first attempts to use the system for real holography and the authors show results of both recorded holograms and the corresponding reconstructed images. Finally, the authors try to analyze the effect that these advances are likely to have on the future prospects for success in applications of x-ray holography and the degree to which the other technical systems that are needed for such success are available or within reach. Nine years (November 1978 to October 1987) of Nimbus-7 Earth radiation budget (ERB) products have shown that the global annual mean emitted longwave, absorbed shortwave, and net radiation were constant to within about + 0.5 W/sq m. Further, most of the small annual variations in the emitted longwave have been shown to be real. To obtain this measurement accuracy, the wide-field-of-view (WFOV) Earth-viewing channels 12 (0.2 to over 50 micrometers), 13 (0.2 to 3.8 micrometers), and 14 (0.7 to 2.8 micrometers) have been characterized in their satellite environment to account for signal variations not considered in the prelaunch calibration equations. Calibration adjustments have been derived for (1) extraterrestrial radiation incident on the detectors, (2) long-term degradation of the sensors, and (3) thermal perturbations within the ERB instrument. The first item is important in all the channels; the second, mainly in channels 13 and 14, and the third, only in channels 13 and 14. The Sun is used as a stable calibration source to monitor the long-term degradation of the various channels. Channel 12, which is reasonably stable to both thermal perturbations and sensor degradation, is used as a reference and calibration transfer agent for the drifting sensitivities of the filtered channels 13 and 14. Redundant calibration procedures were utilized. Laboratory studies complemented analyses of the satellite data. Two nearly independent models were derived to account for the thermal perturbations in channels 13 and 14. The global annual mean terrestrial shortwave and longwave signals proved stable enough to act as secondary calibration sources. Instantaneous measurements may still, at times, be in error by as much as a few Wm(exp -2), but the long-term averages are stable to within a fraction of a Wm(exp -2). Author

The design and test of a prototype presampler suitable for the Zeus calorimeter is described. The energy loss due to the presence of inactive material positioned in front of the Zeus calorimeter prototype is studied for electrons and hadrons in the energy range 10 to 100 GeV. A method to recover the energy loss is described. The correction of the energy loss for electrons and hadrons where the amount of inactive material is not exactly known is calculated. It is shown that the calorimetric energy measurements, after correction with the presampler signal, agrees to within about 1% of the nominal beam energy, with only a minor deterioration in the energy resolution. The presampler information can contribute to the electron hadron identification and position determination in regions where inactive material is positioned in front of the calorimeter. ESA

FAILURE MECHANISMS OF HIGH TEMPERATURE SEMICONDUCTOR LASERS M.S. Thesis
David H. Leicester Dec. 1993 185 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273833; AFIT/GE/ENP/93D-01) Avail: CASI HC A09

The primary intent of this research was to determine the influence of three common degradation mechanisms--dark area defects, facet degradation, and contact degradation--on the operational lifetime of GaAs edge-emitting semiconductor lasers driven by continuous current at 100 C. Inherent to this work was the quantified characterization of the lasers during their operation. This characterization arose as the power output as a function of driving current at room temperature before and after laser exposure to 100 C ambient temperature. These power vs. current characterizations were conducted at room temperature on each laser before and after exposure to 100 C as well as at the beginning and end of each laser's exposure to 100 C. An additional means of examining laser degradation came from measuring the current required over time to maintain a constant power output of 5,7, or 10mW at the elevated temperature. The research demonstrated that facet degradation and contact degradation were minor contributors to the bulk of the data base's degradation. Dark area defects were thus the primary degradation mechanism as the data's gradually increasing current necessary to maintain constant output will attest. An HF acid rinse on one laser, reacting aggressively to local crystal defects, highlighted the growth of dark area defects toward the lasing cavity due to continued lasing. One trend in the data was left unexlained. As a whole, the lasers performed with higher slope efficiencies at elevated temperature, contrary to previously documented research. This topic deserves future research. DTIC

CHARACTERIZATION OF NONLINEAR EFFECTS IN OPTICALLY PUMPED VERTICAL CAVITY SURFACE EMITTING LASERS M.S. Thesis
Scott L. Brown Dec. 1993 93 p
(AD-A273840; AFIT/GEO/ENP/93D-01) Avail: CASI HC A05/MF A01

The nonlinear characteristics of optically pumped Vertical Cavity Surface Emitting Lasers (VCSEL's) are identified, isolated, and quantified. Three different VCSEL's are evaluated including two with gain regions of bulk GaAs operating at 875nm and one multi-quantum well (MQW) InGaAs VCSEL operating at 950nm. The nonlinearities evaluated include those due to cavity temperature, carrier injection, and internal lasing field. The VCSEL's are pumped by a picosecond/femtosecond Ti:Sapphire laser which is configured to operate in CW, gated CW (minimum gate width was 200ns), picosecond, and gated picosecond modes. A linear relationship is shown between wavelength and substrate temperature, cavity temperature, and injected carriers. It is shown that heating is the dominate nonlinearity in the bulk gain region VCSEL's for the pump duty cycles which could be achieved. The MQW VCSEL was dominated by nonlinearities due to carrier population at duty cycles of 10% or less causing the VCSEL to blueshift. A nonlinear relationship is shown between input power and output power and is attributed to the optical Kerr effects in the mirror layers and gain region. DTIC

ULTRA-HIGH AGGREGATE BANDWIDTH TWO-DIMENSIONAL MULTIPLE-WAVELENGTH DIODE LASER ARRAYS Semiannual Progress Report, 10 Apr. - 9 Dec. 1993
Connie Chang-Hasnain 9 Dec. 1993 12 p
(Contract N00014-93-1-0558)
(AD-A274018) Avail: CASI HC A03/MF A01

Two-dimensional (2D) multi-wavelength vertical cavity surface emitting laser (VCSEL) arrays is promising for ultrahigh aggregate capacity optical networks. A 2D VCSEL array emitting 140 distinct wavelengths was reported by implementing a spatially graded layer in the VCSEL structure, which in turn creates a wavelength spread. Concentrtion was on epitaxial growth techniques to make reproducible and repeatable multi-wavelength VCSEL arrays. Our approach to fabricate the spatially graded layer involves creating a nonuniform substrate surface temperature across the wafer during the growth of the cavity spacer region using the fact that the molecular beam epitaxy growth of GaAs is highly sensitive to the substrate temperature. Growth is investigated with the use of a patterned spacer (either a Ga or Si substrate) placed in-between the substrate and its heater. The temperature distribution on such wafers is used to guide our experiments. A reflectivity measurement apparatus that is capable of mapping a 2 in. wafer with a

100 microns diameter resolution was built for diagnosing our wafers. In this first six-month report, our calculations, the various experimental results, and a discussion on future directions are presented. DTIC

(DE93-520378; KEK-Proc-92-12; CONF-9103277) Avail: CASI HC A10/MF A03

This is the record of the lectures given at the free electron laser simulation code workshop held at the National Laboratory for High Energy Physics on 15 Mar. 1991. As a result of the fact that free electron lasers can generate especially powerful and coherent light in the wide wavelength region from long wavelengths, such as microwaves, to short wavelengths, such as X-rays and gamma rays, the interest in free electron lasers has grown in Japan and foreign countries, and new experimentation has been carried out actively. As a result, the necessity for quantitative theoretical calculations using simulations has become paramount. This workshop was held for the express purpose of exchanging information and discussion. Thirty-nine persons took part in the workshop, and 11 lectures were presented. DOE

ELASTIC BACKSCATTERING LIDAR FOR A MSTI SATELLITE
T. W. Meyer, D. M. Alde, and J. L. Banger et al 1993 6 p Presented at the Integrated Record Input System (IRIS) Meeting on Active Systems, Monterey, CA, 2-4 Nov. 1993
(Contract W-7405-eng-36)
(DE94-002701; LA-UR-93-3838; CONF-9311120-1) Avail: CASI HC A02/MF A01 (US Sales Only)

An elastic backscattering lidar is being built for the Ballistic Missile Defense Organization to fly on a MSTI (Miniature Seeker Technology Integration) satellite in low-earth orbit. It is planned that the 90-kg payload be designed, constructed, and tested in a two-year time interval. It features a 76-cm diameter primary light collection mirror and a diode-pumped Nd:YAG laser (1064 nm) emitting 1.5 joules per pulse at a repetition frequency of 50 Hz. The telescope, fixed with respect to the satellite, has a 6 deg field-of-regard, within which a scanning mirror will select the laser beam direction and the field-of-view of 0.5 mr. Other payload elements are the detector (avalanche photodiode) and the R3081-microprocessor-based payload control electronics. This payload will demonstrate the capability of a lidar system on a small satellite to track a theater missile both during boost phase and after burnout. Expected signal amplitudes will be presented, based on available data and on our own measurements of missile plumes with a ground-based lidar. Finally, missile tracking accuracies will be discussed. IMPROVED MEASUREMENT ACCURACY IN A LONG TRACE PROFILER: COMPENSATION FOR LASER POINTING INSTABILITY
S. C. Irick 2 Aug. 1993 9 p Presented at the Synchrotron Radiation Instrumentation, Gaithersburg, MD, 23-26 Aug. 1993
(Contract DE-AC03-76SF-00098)
(DE94-003408; LBL-34603; CONF-930824-27) Avail: CASI HC A02/MF A01

Laser pointing instability adds to the error of slope measurements taken with the Long Trace Profiler (LTP). As with carriage pitch error, this laser pointing error must be accounted for and subtracted from the surface under test (SUT) slope measurement. In the past, a separate reference beam (REF) allowed characterization of the component of slope error from carriage pitch. However, the component of slope error from laser pointing manifests itself differently in the SUT measured slope. An analysis of angle error propagation is given, and the effect of these errors on measured slope is determined. Then a method is proposed for identifying these errors and subtracting them from the measured SUT slope function. Separate measurements of carriage pitch and laser pointing instability isolate these effects, so that the effectiveness of the error identification algorithm may be demonstrated. DOE

BROAD BAND TUNABLE DYE LASER DEVELOPMENT
Jong Min Lee, Jung Bog Kim, Sung Ho Kim, Do Kyung Go, Chang Hwan Lim, Si Pyo Rho, Kyu Seok Song, Byung Cheol Lee, Jong Hoon Rhi, and Jae Min Han et al Dec. 1992 81 p In KOREAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-632978; KAERI/RR-1143/92) Avail: CASI HC A05 (US Sales Only)

The technical goal and objectives are the development of a tunable laser which can be tuned from UV to near IR and commercialization for uses in various fields. Two kinds of resonators are developed. The user can select one resonator and change into the other without changing other parts. GIM type has a linewidth of 5 GHz which is able to be used usually, and a SLM type which has a very narrow linewidth of less than 1 GHz. Each system can have one or two amplifiers depending on output power or cost. High stability and safety, cost-down, and modules into about 30 components have been tried. We hope that this laser can help developments in researches of university, industry, and institute. DOE

THE DEVELOPMENT OF Cr, Tm, Ho:YAG LASERS FOR AIRBORNE LIDAR Final Report, 22 Jul. 1991 - 21 Jan. 1993
John H. Flint 22 Feb. 1993 29 p
(Contract F19628-91-C-0119)
(AD-A274895; PL-TR-93-2035; AD-E201724) Avail: CASI HC A03/MF A01

A research effort was conducted to determine the physical principles limiting the performance of pulsed Cr,Tm,Ho:YAG (CTH:YAG) lasers. The project was to conclude with the design of an eye-safe, aircraft-based transmitter for LIDAR and other remote sensing applications. The target specifications of the laser were: 100 mJ at 10 Hz repetition rate, single longitudinal mode, with a minimum pulse width of 500 ns. The research program investigated Q-switched operation of CTH:YAG lasers, flashlamp-pumped amplifiers, and injection seeding using diode-laser-pumped, single-frequency TH-YAG lasers. Up to 30 mJ was extracted in a TEM(sub 00) pulse at 10 Hz from both linear and ring resonators. The pulse widths at 30 mJ ranged from 200 ns to 400 ns. Injection-seeding of a ring resonator operating at 10 mJ per pulse at 7 Hz was demonstrated, and the output of this laser was amplified by a factor of three. The final task of this research program, the design of an aircraft-based transmitter, was incomplete at the end of the contract period. DTIC

DEVELOPMENT OF AN INDUSTRIAL CO2 LASER FOR MASK MARKING
Cheol Jung Kim, Chin Mann Jung, Jeong Mook Kim, Kwang Suk Kim, Seong Ouk Kwon, Sang Mock Lee, and Duk Hyun Kim Jun. 1992 84 p In KOREAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-632901; KAERI/RR-1125/92) Avail: CASI HC A05 (US Sales Only)

We developed and commercialized an industrial pulsed TEA CO2 laser with high power and high repetition rate for printing characters and figures. Several commercial models have been investigated in design and performance. We improved its quality to the level of commercial TEA CO2 laser by an endurance test for each parts of laser system. The maximum pulse energy and repetition rate of our laser were above 5 J/pulse and 20 pps, respectively. Moreover, we designed the resolving power could be possible to 10 line/mm. Many optical parts were localized and lowered much in cost. Only few parts were imported and almost 90% in cost were localized. Also, to accelerate the commercialization by the joint company, the training and transfer of technology were pursued in the joint participation in design and assembly by company researchers from the early stage. DEVELOPMENT OF SURGICAL CW Nd:YAG LASER WITH OPTICAL FIBER DELIVERY SYSTEM

Cheol Jung Kim, Jeong Mook Kim, Chin Mann Jung, Kwang Suk Kim, Min Suk Kim, Jae Wan Cho, and Duk Hyun Kim Jun. 1992 114 p In KOREAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(DE93-632902; KAERI/RR-1126/92) Avail: CASI HC A06 (US Sales Only)

We developed a surgical CW Nd:YAG laser with optical fiber delivery system. Several commercial models have been investigated in design and performance. We improved its quality to the level of commercial Nd:YAG laser by an endurance test for each parts of laser system. The maximum power of our surgical laser was 150 W and the laser pulse width could be controlled to 99 sec continuously by 0.1 sec. Many optical parts were localized and lowered much in cost. Only a few parts were imported and almost 90% in cost were localized. Also, to find out the maintenance problem of this surgical laser, it was applicated to the production line of our joint company. LASER-BASED COMMUNICATION LINK [LASERBASERT KOMMUNIKASJONSLINK]

Knut Stenersen, Stig Landroe, and Oeyvind Christensen 15 Apr. 1993 17 p In NORWEGIAN

(FFI-93/7023; ETN-94-95210) Avail: CASI HC A03/MF A01

A prototype of a laser based communication link for point to point transmission of data through the atmosphere is described. The link has a laser transmitter and a receiver at each end, which allows full duplex communication. The link has a EUROCOM B interface and can be used for transmission of 512 kbit/s data between two switches in the Norwegian military tactical communication system TADKOM. The data are transmitted through the air as FSK (Frequency Shift Keying) modulated laser light. The laser transmitter is an eyesafe 10 mW diode laser with 1.55 micrometer wavelength. The transmitter and receiver lobes have an angular divergence of about 1.5 mrad, and the system requires an alignment accuracy of better than 0.5 mrad for good performance. The maximum range of the link is slightly larger than the optical visibility for optical visibilities below 2 km. For 10 km visibility the maximum range is about 5 km. Based on available visibility statistics, it was calculated that a 1 km link should be in operation 97 to 99% of the time (average over one year) for typical locations in Norway. The link was tested with TADKOM equipment in laboratory. ESA

LASER MANIPULATION OF METASTABLE NEON ATOMS Ph.D. Thesis

Maarten Dirk Hoogerland 1993 96 p Sponsored by Stichting voor Fundamenteel Onderzoek der Materie

(ETN-94-95344) Avail: CASI HC A05/MF A01

The force that laser light exerts on neutral atoms is studied. The design, the tests and the operation of an atomic beam brightener are discussed. Doppler cooling to intensify a beam of metastable ((3s)-3(P(sub 2))) neon atoms by applying it into two dimensions is used. In order to increase the capture range of the cooling processs, curved wavefronts, keeping the angle between the laser beam and the atom trajectory at a fixed value, are used. The effects of running and standing laser fields on an ensemble of atoms with a well defined initial velocity by atomic beam deflection are studied. The deflection of a well collimated atomic beam of metastable neon atoms by a running laser wave is considered. Results giving the deviation of photon statistics of the resonance fluorescence from Poissonian statistics as a function of laser detuning and laser intensity are given. The results are compared to the results of a numerical simulation, showing excellent agreement. The first force and diffusion measurements on sub Doppler cooling processes are presented. The deflection of a well collimated atomic beam of metastable neon atoms by a short interaction with a (quasi) standing wave is investigated. ESA

COMPACT, SOLID-STATE FEMTOSECOND SOURCE Final Report, Nov. 1992 - May 1993

Philippe Bado Oct. 1993 80 p

(Contract F30602-93-C0041)

(AD-A273932; RL-TR-93-188) Avail: CASI HC A05/MF A01

The goal of this program was to demonstrate that femtosecond laser sources (1 femtosecond = 10(exp -15) sec) can be made to be extremely compact and robust. We demonstrated the generation of ultrashort pulses using compact diode-pumped lasers. Our latest pump source is 300 times smaller and weighs only a fraction of today's commercial equivalent. It runs on 110 VAC and requires no water cooling. The commercial availability of robust sources will have a broad commercial impact. A brief listing includes: industry (3D imaging, ranging, thin-film monitoring, optical memory), medical (confocal microscopy, real-time assessment of surgical procedure), and military (sensor fusion, high-power THz beam generation, phase-array radars). We are pursuing the development of a general laboratory instrument, as well as several specific applications. This large market has not gone unnoticed: Japan's Ministry of International Trade and Industry (MITT) has very recently recommended Femtosecond Technology as one of Japan's only six priority research areas. STUDY ON LASER ATOMIC SPECTROSCOPY

Hyung Ki Cha, Kyu Seok Song, Do Young Jeong, Jong min Lee, Jong Hoon Yi, and Jung Bok Kim Jan. 1993 124 p In KOREAN

(DE93-633328; KAERI/RR-1166/92) Avail: CASI HC A06/MF A02 (US Sales Only)

Laser atomic spectroscopic study on actinium element has been performed in many areas of spectroscopy. The study on characteristic of atomic vapor has been proceeded for copper atom and the spatial density distribution of copper vapor is measured. This experimental data has been compared with the theoretically calculated data. In spectroscopic experiment, the first and second excited states for actinium element are identified and the most efficient ionization scheme for actinium element is identified. In addition, the corrosion problem for filament material due to the heating of the actinium element has been studied. DOE

DEVELOPMENT OF REAL-TIME PULSE SHAPING TECHNOLOGY IN SOLID-STATE LASERS

Cheol Jung Kim, Jeong Mook Kim, Chin Mann Jung, Kwang Suk Kim, Min Suk Kim, Jae Wan Cho, and Duk Hyun Kim Feb. 1993 147 p In KOREAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(DE93-633438; KAERI/RR-1207/92) Avail: CASI HC A07 (US Sales Only)

Real-time pulse shaping technology in solid state lasers was developed for special cutting and welding applications. The real-time pulse shaping unit has the capability of 20 step variation in laser intensity, 200 steps in laser pulse width, and 16 pulse shape patterns with MOSFET pulse width modulation method. Also, a previous 250 W class Nd:YAG laser system was improved by using this new technology. Many optical parts were localized and lowered in cost. Only a few parts were imported and almost 90% of costs were localized. Also, to accelerate the commercialization by the joint company, the training and transfer of technology were pursued in the joint participation in design and assembly by company researchers from the early stage. Two Nd:YAG lasers have been assembled and will be tested in industrial manufacturing processes to prove the capability of developed Nd:YAG laser with potential users. DOE

LASER DOPPLER VELOCIMETRY IN A LOW SPEED MULTISTAGE COMPRESSOR M.S. Thesis
Joseph M. Utschig 23 Sep. 1993 97 p
(AD-A274836) Avail: CASI HC A05/MF A02

Two-dimensional Laser Doppler Velocimetry (LDV) measurements were taken in the Low Speed Multistage Compressor (LSMSC) with data indexed to the rotor position. Laser measurements were conducted at two axial positions downstream of the second rotor and one axial position downstream of the second stator. The entire rotor periphery was measured at fixed radial displacements at each location and ensemble averaged. The survey downstream of the stator attempted to quantify the unsteady flow of the stator passage. Attempts were made to quantify the absolute flow angle behind both the rotor and the stator and compare them to pneumatic data collected at the same axial and circumferential positions, respectively. Absolute flow angles calculated from the laser measurements were in agreement with pneumatic probe data. In addition, the surveys were conducted in an attempt to quantify the velocity profile from the rotor passage. The laser surveys indicated distinct and repeatable patterns in both the axial and circumferential components of the rotor exit velocity. Data downstream of the stator proved inconclusive. DTIC

DISTRIBUTED Nd:YAG LASER WELDING AND PROCESS CONTROL IN INERT GLOVE BOXES
J. O. Milewski, G. K. Lewis, M. R. Barbe, and D. A. Cremers 1993 7 p Presented at the American Welding Society International Conference on Modeling and Control of Joining Processes, Orlando, FL, 8 Dec. 1993
(Contract W-7405-eng-36)
(DE94-002629; LA-UR-93-3545; CONF-931234-3) Avail: CASI HC A02/MF A01

The authors have fabricated and assembled a fiber optic delivered Nd:YAG laser welding work station that consists of three glove boxes served by a single 1 kw laser. Processing considerations related to the welding of special nuclear materials, toxic materials, and complex part geometry are addressed within each work cell. The authors are proceeding with a development effort to integrate the equipment capabilities with remote sensing, process monitoring, and control systems. These systems will provide real time data acquisition during welding, monitoring and verification of weld parameters, and CAD/CAM to computer numerical control generated positioning paths. Computerized information storage, retrieval, and network methods are used for weld process documentation and data analysis. A virtual control panel is being configured to integrate the monitoring and control operation of individual subsystems, such as laser and motion control, into a single graphical interface. Development work on sensors to monitor laser beam characteristics and weld depth in real time with potential for adaptive control is in progress. System capabilities and results of these development efforts are presented. DOE

CALCULATIONS OF POPULATION TRANSFER DURING INTENSE LASER PULSES
K. J. Schafer and K. C. Kulander Aug. 1993 8 p Presented at the 6th International Conference on Multiphoton Processes, Quebec City, Quebec, 25-30 Jun. 1993
(Contract W-7405-eng-48)
(DE94-001060; UCRL-JC-114310; CONF-9306125-6) Avail: CASI HC A02/MF A01

Recent experiments by several groups have examined the question of population transfer to resonantly excited states during intense short laser pulses, in particular the amount of population that remains 'trapped' in excited states at the end of a laser pulse. Calculations of population transfer and resonant ionization in xenon at both 660 and 620 nm are presented. At the longer wavelength, the seven photon channel closes at 2.5 x 10(exp 13) W/cm(exp 2). Pulses with peak intensities higher than this result in 'Rydberg trapping', the resonant transfer of population to a broad range of high-lying states. The amount of population transferred depends on both the peak intensity and pulse duration. At 620 mm there are numerous possible six photon resonances to states with p or f angular momentum. A large number of calculations were performed for 40 fs pulses at different peak intensities and the population transferred to these low-lying resonant states were examined as a function of the peak laser intensity. We do not have room to comment upon the resonantly enhanced ionized electron energy spectra that we also determine in the same calculations. Our calculations involve the direct numerical integration of the time-dependent Schroedinger equation for an atom interacting with a strong laser field. The time-dependent wave function of a given valence electron is calculated on a spatial grid using a one-electron pseudo potential. This single active electron approximation (SAE) was shown to be a good approximation for the rare gases at the intensities and wavelengths that we will consider. The SAE potential used has an explicit angular momentum dependence which allows us to reproduce all of the excited state energies for xenon quite well. DOE

PHASE CONJUGATION AND PULSE COMPRESSION OF HIGH ENERGY LASERS: FROM NANOSECONDS TO MICROSECONDS
C. B. Dane and L. A. Hackel 1 Jun. 1993 5 p Presented at the 2nd International School and Topical Meeting on Applications of Nonlinear Optics, Prague, Czechoslovakia, 16-20 Aug. 1993
(Contract W-7405-eng-48)
(DE94-001061; UCRL-JC-114059; CONF-9308186-1) Avail: CASI HC A01/MF A01

SBS phase conjugation is playing a crucial role in the scaling of solid state laser systems to high average power. Amplifier systems with near diffraction limited beam quality were demonstrated with average power outputs of 100W in Nd:glass and Nd:YAG. Wavefront correction provided by an SBS phase conjugate mirror not only significantly lowers the output divergence of the laser, it also increases the maximum average power obtainable by preventing damage to optical components caused by distortion of the beam profile due to uncorrected thermally induced aberrations. The output pulsewidth format required for applications of high average power pulsed solid state lasers is extremely varied, ranging from below a nanosecond to many microseconds. However, most demonstrated applications of SBS phase conjugation to high average power laser systems have involved the amplification of typical Q-switched oscillator pulses of 7-30 ns in duration. Based on the requirements imposed by specific applications for high average power solid state laser systems, the operation of SBS phase conjugated amplifier systems with output pulsewidths ranging from 1 ns to 1 microns were investigated and demonstrated. The specific considerations for the various pulsewidth regimes as well as details of the experimental investigations are presented. DOE

DEVELOPMENT OF LASERS OPTIMIZED FOR PUMPING Ti:Al2O3 LASERS Final Technical Report, 10 Apr. 1991 - 17 Dec. 1993

Glen A. Rines and Richard A. Schwarz Mar. 1994 103 p
(Contract NAS1-19304; RTOP 324-02-03)
(NASA-CR-4573; NAS 1.26:4573) Avail: CASI HC A06/MF A02

Laboratory demonstrations that were completed included: (1) an all-solid-state, broadly tunable, single-frequency, Ti:Al2O3 master oscillator, and (2) a technique for obtaining 'long' (nominally 100- to 200-ns FWHM) laser pulses from a Q-switched, Nd oscillator at energy levels commensurate with straightforward amplification to the joule level. A diode-laser-pumped, Nd:YLF laser with intracavity SHG was designed, constructed, and evaluated. With this laser greater than 0.9 W of CW, output power at 523.5 nm with 10 W of diode-laser pump power delivered to the Nd:YLF crystal was obtained. With this laser as a pump source, for the first time, to our knowledge, an all solid-state, single frequency, Ti:Al203 laser with sufficient output power to injection seed a high-energy oscillator over a 20-nm bandwidth was demonstrated. The pulsed laser work succeeded in demonstrating pulse-stretching in a Q-switched Nd:YAG oscillator. Pulse energies greater than 50-mJ were obtained in pulses with 100- to 200-ns pulsewidths (FWHM). Author (revised)

BEAM-QUALITY MEASUREMENTS FOR MATERIALS PROCESSING LASERS AND THE PROPOSED ISO STANDARD
P. W. Fuerschbach and M. Essien 1993 12 p Presented at the 1993 International Congress on Application of Lasers and Electro-Optics, Orlando, FL, 24-28 Oct. 1993
(Contract DE-AC04-94AL-85000)
(DE94-002738; SAND-93-1331C; CONF-9310194-2) Avail: CASI HC A03/MF A01

Laser beam-quality can indicate the maximum power density that can be obtained with a specific laser and serves as a figure-of-merit when comparing lasers, calibrating lasers, and in assessing a laser's operating condition. Measurements of laser beam-quality for a 1000 watt continuous wave CO2 laser and a 400 watt pulsed Nd:YAG laser have been completed. These measurements were made with two different type instruments: (1) a specially constructed apparatus that uses an integrating sphere and diamond apertures and (2) a commercially available instrument that incorporates a scanning and spinning hollow needle. Laser beam-quality and the propagation constants have been determined using a non-linear curve-fitting technique and the new proposed ISO standard for measuring laser beam-quality. The curve fitting analysis and the ISO analysis were found to produce approximately the same values for beam-quality and the propagation constants. However, a comparison of the experimental procedures required with the two techniques showed significant differences. The utility of the ISO technique was limited by it's experimental procedural restrictions. The importance of spherical aberration in distorting laser beam-quality measurements and in limiting the application of beam-quality to laser spotsize prediction is also detailed. DOE

OPTIMUM FOR THE GASDYNAMIC SYSTEM IN A FAST-AXIAL-FLOW CO2 LASER
Chengwu An, Shimin Li, Qisheng He, and Zaiguang Li 9 Dec. 1993 15 p Transl. into ENGLISH from Jiguang Zazhi (China), v. 10, no. 2, 1989 p 53-56
(AD-A274305; FASTC-ID(RS)T-0123-93) Avail: CASI HC A03/MF A01

It is reported that the temperature rise of the discharge mixture, in a fast-axial-flow CO2 laser, can be decreased by increasing both the mass flow rate and the speed of the mixture through the laser tube. However, increasing the mixture speed, in a practical gas dynamic system, will lead to decreasing the mass flow rate, and thus the discharge tube with appropriate cross section, which matches the properties of the given blower driving the mixture to flow, should be chosen to obtain the optimal operation of the laser. PHASE CONJUGATED LASERS APPLIED TO COMMERCIAL X RAY LITHOGRAPHY
L. A. Hackel, C. B. Dane, M. R. Hermann, and L. E. Zapata 1 Jun. 1993 6 p Presented at the 2nd International School and Topical Meeting on Applications of Nonlinear Optics, Prague, Czechoslovakia, 16-20 Aug. 1993
(Contract W-7405-eng-48)
(DE94-001529; UCRL-JC-114058; CONF-9308186-2) Avail: CASI HC A02/MF A01

Over the last 20 years lasers have been a useful tool in the generation of x-ray radiation. Recent technology advances have allowed solid state lasers to be designed as a drive source for proximity print x-ray lithography systems as well as in the longer term for soft x-ray projection lithography systems. In addition the ability to build multi-hundred joule per pulse, several nanosecond pulselength lasers with repetition rate capability and table top size now allow us to design table top x-ray sources and x-ray lasers. Within our laboratory several high power solid state lasers are being built for direct application to these systems. It was found that the best performance of these high power lasers is obtained when non-linear phase conjugate mirrors are included. These mirrors function in two important respects; they provide a means to obtain very high beam brightness without the generation of hot spots which damage optical components and in addition because of their threshold activation characteristic they function in the role of multistage gain isolators. The design and performance of two systems which are being hardened for commercialization and a third system which is in the design phase and will be used as a pump source for an x-ray laser are described in detail. LASER PHASE INDUCED INTENSITY NOISE IN FIBER-OPTIC SIGNAL PROCESSING AND SENSING SYSTEMS Ph.D. Thesis
Ady Arie Mar. 1991 142 p
(ITN-94-85234) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

The effects of random phase fluctuations in laser output on the performance of optical systems was studied. The statistical nature of phase induced intensity noise (PIIN) was measured and analysed by studying its probability density function and the second and fourth moments of the optical field at the output of several multiple path systems. The properties of the semiconductor laser, including broad spectral linewidth and non-Lorentzian line shape were shown to have significant influence on the generated PIIN. The PIIN statistics was first studied via the probability density function (PDF) of the beat signal obtained from a two-beam interferometer fed by the laser. Two distinct operating regimes could be defined, according to the ratio between the interferometer delay and the laser coherence time. Analytical expressions were obtained for statistical averages of the PIIN at the output of a general multiple path system; they represent the variance and autocovariance, and the power spectral density of the PIIN at the system output. The non-Lorentzian lineshape of the semiconductor laser was taken into account and the results obtained were found to differ from the Lorentzian model predictions; power spectrum measurements by means of a Mach-Zehnder interferometer confirmed the theoretical model. Analysis of the PIIN for complex signal processing systems comprising several subsystems showed that the PIIN spectrum was determined by two mechanisms: noise generation and noise filtration. ISA

KINOFORM/LENS SYSTEM FOR INJECTING A HIGH POWER LASER BEAM INTO AN OPTICAL FIBER
W. C. Sweatt and M. W. Farn (Massachusetts Inst. of Tech., Lexington.) 1993 29 p Presented at the 25th Boulder Damage Symposium: Annual Symposium on Optical Materials for High-Power Lasers, Boulder, CO, 27-29 Oct. 1993 Limited Reproducibility: More than 20% of this document may

be affected by poor print
(Contract DE-AC04-94AL-85000)
(DE94-003226; SAND-93-2144C; CONF-931054-1) Avail: Issuing Activity (Department of Energy (DOE))

A method for injecting a high peak power multimode YAG laser beam into an optical fiber has been developed. The design minimizes the peak irradiance on the fiber's entrance face and reduces its dependence on the laser's mode structure and the system alignment. A simple lens and a specially designed kinoform (or binary optics element) operate together to transform a 5 mm diameter laser beam into two concentric ring foci that fit on the 400 micron diameter fiber face. TECHNICAL REPORT OF ISSP. SER. A, NO. 2686: HIGH-ORDER HARMONIC GENERATION AND IONIZATION USING ULTRASHORT KrF AND Ti:SAPPHIRE LASERS
Kiminori Kondo, Taichiro Tamida, Nabekawa Yasuo, and Shuntaro Watanabe Jun. 1993 39 p
(ISSN 0082-4798)
(JTN-94-80572) Avail: CASI HC A03/MF A01

High-order harmonic generation in KrF and Ti:sapphire lasers is analyzed with an emphasis on the contribution of multiple-charged ions. It is confirmed that the intensity dependence of the ion yield of multiple-charge states is explained by ADK (Ammosov-Delone-Krainov) tunneling theory, regardless of the wavelength. The harmonic distributions are compared with the single-atom responses calculated using the short-range potential model with the effective interaction intensity determined by ADK tunneling theory. From this analysis, the harmonics above the 21st in Ne and above the 13th in Ar for the KrF laser are found to be due to double-charged ions. Author (NASDA)

LASER SURFACE MODIFICATION OF INTERMETALLIC COMPOUNDS
M. P. Graham, H. W. Kerr, and D. C. Weckman Feb. 1992 90 p
(DREA-CR-92-416; DSIS-94-00040; CTN-94-61127) Avail: CASI HC A05/MF A01

The rare earth compound Terfenol-D (Tb(x)Dy(1-x)Fe(y), where x = 0.3 and y = 1.95) has highly magnetostrictive strain properties, but is very brittle and can be difficult to manufacture into functional components. A study was conducted to investigate the effects of laser surface modification of this intermetallic compound in order to determine if the rapid solidification following laser melting could produce a surface with improved toughness. The effects of various pulsed Nd:Y-Al garnet laser process parameters on the resultant surface pool diameter, penetration, and quality were studied experimentally. Individual spots were made on a carefully prepared butt joint at a mean laser power of 180 W. Conduction mode and keyhole mode pools were observed, and the quality of the specimens was poor. Experiments at 60 W and 180 W laser power were also conducted on bulk material. Different processing approaches were used, including manipulating focal position, temporal pulse shaping, using multiple pulses per shot, and preheating the specimens. Surface quality was improved in specimens processed with a temporal pulse shape consisting of a gentle pre-pulse followed by the balance of energy, and by specimens preheated to 150 and 450 C. Multiple pulses per shot on preheated (150 C) specimens also improved surface quality. Author (CISTI)

LASER BLOW-OFF LITHIUM BEAM PROBING WITH HIGH TEMPORAL RESOLUTION FOR EDGE PLASMA DIAGNOSTICS
S. Sasaki, S. Takamura, Y. Uesugi, Y. Ohkouchi, and K. Kadota Apr. 1993 22 p
(DE94-701176; PSC-28) Avail: CASI HC A03/MF A01

Laser blow-off neutral lithium beam probing with high temporal resolution has been developed to measure edge electron density profiles in a plasma. A new electron density reconstruction method, taking account of the transport of a laser blow-off beam in the plasma, improved the accuracy of the density measurement. The use of a camera system with gate function makes it possible to measure the density profile with high temporal resolution of approximately 10 to 50 microseconds. The optimum condition for shuttering timing and period to observe Li I emission profile is discussed from the viewpoints of the beam penetration into the plasma and the accuracy of measurement. A rapid temporal evolution of edge electron density profile during the limiter biasing in a small tokamak HYBTOK-II is successfully obtained by this system. DOE

A tunable erbium doped fiber ring laser, pumped with a 980 nm diode laser, was constructed. Output power as a function of pump power and output wavelength for a given fiber length was measured. Spectral and temporal analysis of the signal showed mode-locked pulses of short duration and broad frequency content, as well as a continuous wave (CW) component confined to a relatively narrow optical frequency range. The mechanisms for this type of mode-locking are discussed as well as the limitations placed on the lasing line width and spectral tunability. DTIC

A treadmill has been developed to support our cockroach locomotion studies. We have developed a small treadmill with a transparent belt for studying leg joint movements along with EMG's as the animal walks or runs at various speeds. This allows us to match the electrical activity in muscles with the kinematics of joint movement. Along with intracellular stimulation studies performed previously, the tools are now in place to make major advances in understanding how the insect's walking movements are actually accomplished. STRUCTURAL ANALYSIS OF A FRANGIBLE NUT USED ON THE NASA SPACE SHUTTLE
K. E. Metzinger Nov. 1993 23 p
(Contract DE-AC04-94AL-85000)
(DE94-003672; SAND-93-1720) Avail: CASI HC A03/MF A01

A structural analysis methodology has been developed for the NASA 2.5-inch frangible nut used on the Space Shuttle. Two of these nuts are used to secure the External Tank to the aft end of the Orbiter. Both nuts must completely fracture before the Orbiter can safely separate from the External Tank. Ideally, only one of the two explosive boosters contained in each nut must detonate to completely break a nut. However, after an uncontrolled change in the Inconel 718 material processing, recent tests indicate that in certain circumstances both boosters may be required. This report details the material characterization and subsequent structural analyses of nuts manufactured from two lots of Inconel 718. The nuts from the HSX lot were observed to consistently separate with only one booster, while the nuts from the HBT lot never completely fracture with a single booster. The material characterization requires only tensile test data and the determination of a tearing parameter based on a computer simulation of a tensile test. Subsequent structural analyses using the PRONTO2D finite element code correctly predict the differing response of nuts fabricated from these two lots. This agreement is important because it demonstrates that this technique can be used to screen lots of Inconel 718 before manufacturing frangible nuts from them. To put this new capability to practice, Sandia personnel have transferred this technology to the Pyrotechnics Group at NASA-JSC. DOE

While most previous work in planning manipulation tasks has relied on the assumption of quasi-static conditions, there can be situations where the quasistatic assumption may not hold, and the assumptions about the environment must be relaxed. This is true, for example, in a situation where objects are making and breaking contact at high enough velocities that contact dynamics play a significant effect in the motion of the colliding objects. There has been some work studying models of collision, in particular for the design and analysis of systems with intermittent constraints, and for the design of juggling robots. Our work extends previous studies in planar juggling to the case of a polygonal object, using the model of rigid body impulsive collision. Simulations verify the results of a linearized analysis. AUTOMATIC ASSEMBLY PLANNING AND ITS ROLE IN AGILE MANUFACTURING: A SANDIA PERSPECTIVE
R. E. Jones and S. G. Kaufman 1993 6 p Presented at the 1st Annual Agile Manufacturing Conference, Albuquerque, NM, 14-15 Oct. 1993
(Contract DE-AC04-94AL-85000)
(DE94-002291; SAND-93-2360C; CONF-9310217-1) Avail: CASI HC A02/MF A01

Sandia was studying automatic assembly planning of electromechanical devices for some years, based on an implemented system called Archimedes. Work done to date has focused on automatic generation of high-level plans, and translation of these plans into robotic control code and workcell layout. More recently, the importance of an assembly planning capability as a design aid has been emphasized, as it could potentially provide early feedback to a designer on the manufacturability of the design. The work done on assembly planning to date, plans for extending it, and its applications to agile manufacturing are described. In particular, an agile manufacturing demonstration project underway at Sandia, and the role the Archimedes assembly planning system will play in it are described. DOE

(DE94-000885; LA-UR-93-3425; CONF-931234-1) Avail: CASI HC A03/MF A01

Electric power for the Cassini space probe will be provided by radioisotope thermoelectric generators (RTG's) thermally driven by General-Purpose Heat Source (GPHS) modules. Each GPHS module contains four, 150-g, pellets of Pu-238O2, and each of the four pellets is encapsulated within a thin-wall iridium-alloy shell. GTA girth welding of these capsules is performed at Los Alamos National Laboratory (LANL) on an automated, digitally-controlled welding system. Baseline design considerations for system automation and strategies employed to maximize process yield, improve process consistency, and generate required quality assurance information are discussed. Design of the automated girth welding system was driven by a number of factors which militated for precise parametric control and data acquisition. Foremost among these factors was the extraordinary value of the capsule components. In addition, DOE order 5700.6B, which took effect on 23 Sep. 1986, required that all operations adhere to strict levels of process quality assurance. A detailed technical specification for the GPHS welding system was developed on the basis of a joint LANL/Westinghouse Savannah River Company (WSRC) design effort. After a competitive bidding process, Jetline Engineering, Inc., of Irvine, California, was selected as the system manufacturer. During the period over which four identical welding systems were fabricated, very close liason was maintained between the LANL/WSRC technical representatives and the vendor. The level of rapport was outstanding, and the end result was the 1990 delivery of four systems that met or exceeded all specification requirements. DOE

The Robotic All-Terrain Lunar Exploration Rover (RATLER) is a four wheeled all-wheel-drive dual-body vehicle. A uniquely simple method of chassis articulation is employed which allows all four wheels to remain in contact with the ground, even while climbing over step-like obstacles as large as 1.3 wheel diameters. The RATLER design concept began at Sandia National Laboratories in late 1991 with a series of small, proof-of-principle, working scale models. The models proved the viability of the concept for high mobility through mechanical simplicity, and eventually received internal funding at Sandia National Laboratories for full scale, proof-of-concept prototype development. Whereas the proof-of-principle models demonstrated the mechanical design's capabilities for mobility, the full scale for experiments in telerobotics, autonomous robotic operations, and telerobotic field geology is described, including an outline of the program's work over the past year, recent accomplishments, and plans for follow-on development work. THE STUDY OF SINGLE-PASS GMA WELDS WITH DIFFERENT COVER GAS COMPOSITIONS ON HSLA-100 STEEL M.S. Thesis

Ricky A. Seravia 23 Sep. 1993 73 p
(AD-A274857) Avail: CASI HC A04/MF A01

This study investigated the effect of varying cover gas compositions on the microstructure and mechanical properties of single run gas-metal arc welds (GMAW) on HSLA-100 plate. Seven different cover gas compositions containing varying amounts of argon, oxygen, and carbon dioxide were evaluated. A statistical and quantitative analysis of the nonmetallic inclusions in the weld metal was performed by scanning electron microscopy (SEM) and energy dispersive analysis of x rays (EDX). These results show that increasing the oxygen content of the cover gas reduces the inclusion size but increases the number density compared with pure argon cover gas, and that this is reflected in the weld metal microstructure since increasing amounts of acicular ferrite were detected predominantly to be of the spessartite composition (3MnO, Al2O3, 3SiO2). As a result of increasing cover gas oxygen, the strength of the weld metal appeared to be lowered due to the oxidation of aluminum, silicon, manganese, and possibly titanium. In addition, the toughness was improved for weld metal generated from cover gases containing oxygen because the ductile-to-brittle transition temperature was lowered by the increasing amounts of acicular ferrite. A METHOD FOR TESTING OF HVAC AUTOMATION EQUIPMENT USING THE EMULATOR AND THE APPLICATION OF THE METHOD [LVI-AUTOMAATIOLAITTEIDEN EMULAATTORITESTAUKSEN TESTAUSMENETTELY JA SEN SOVELTAMINEN]

Satu Kaerki Dec. 1992 160 p In FINNISH Sponsored by Ministry of Trade and Industry, Finland
(ISSN 1235-0605)
(VTT-TIED-1435; ISBN-951-38-4329-7; ETN-94-95262) Copyright Avail: CASI HC A08/MF A02

A testing method for testing HVAC automation equipment with the emulator is presented. The testing method is applied to two alternative supervisory control strategies of an air conditioning plant. In the testing method the advance of testing is described step by step from determining processes to evaluation of the behavior of automation equipment. For testing automation equipment with the emulator, an evaluation method was developed based on weighting factors for grading automation equipment and for tested equipment to make it easier for builders and designers to compare the equipment of different manufactures. The evaluation method is mainly intended for use in testing, but it can possibly be used also as a basis for developing evaluation methods for other purposes. Evaluation methods and criteria that appeared in international literature were used as starting points for developing the evaluation method. In the comparison tests between the supervisory control strategies of an air conditioning plant, the testing method was found to advance in a logical, easily observable order. The results of the comparison tests were analyzed both in the conventional way with the help of graphical formulas and statistical values as well as with the evaluation method developed. The same kinds of conclusions were obtained with both analyzing methods. Hence at least on the basis of these tests, the evaluation method developed gives a rather reliable image of the control functions of automation equipment. ESA

PUMP CFD CODE VALIDATION TESTS Final Report, May 1991 - Dec. 1993

L. A. Brozowski 15 Dec. 1993 30 p Original contains color illustrations
(Contract NAS8-38864)
(NASA-CR-193939; NAS 1.26:193939; RI/RD-93-195) Avail: CASI HC A03/MF A01

Pump CFD code validation tests were accomplished by obtaining nonintrusive flow characteristic data at key locations in generic current liquid rocket engine turbopump configurations. Data were obtained with a laser two-focus (L2F) velocimeter at scaled design flow. Three components were surveyed: a 1970's-designed impeller, a 1990's-designed impeller, and a four-bladed unshrouded inducer. Two-dimensional velocities were measured upstream and downstream of the two impellers. Three-dimensional velocities were measured upstream, downstream, and within the blade row of the unshrouded inducer. Author

MOTION PLANNING FOR SERIAL MANIPULATORS WITH MANY DEGREES OF FREEDOM: IMPLEMENTATION OF A SEQUENTIAL SEARCH STRATEGY M.S. Thesis

Zhenping Guo Jan. 1992 118 p
(ISBN-0-315-83682-2; CTN-94-61032) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A motion planner has been developed and implemented which can plan collision-free motions for serial manipulator arms with many degrees of freedom among stationary obstacles. The planner is based on a sequential search strategy that exploits the serial nature of manipulator arms. The motion of each link is planned successively starting from the base link. Given that the motion of links until link i has been planned, the motion of link i+1 is now planned along this collision-free path by controlling the degree of freedom associated with it. In the simplest case, this strategy results in one one-dimensional (the first link is degenerate) and n-1 two-dimensional planning problems instead of one n-dimensional problem for an n-link manipulator arm. The search strategy leads to a fast and efficient algorithm, and is especially suited for manipulator arms with many degrees of freedom. Furthermore, a backtracking mechanism has been incorporated in the planner which makes it more effective, but slower, in cluttered environments. This mechanism provides a parameter which can be used to trade off completeness of the planner with its speed. The effectiveness of the planner strategy is demonstrated with examples of motion planning for several arms with many degrees of freedom. Author (CISTI)

OPTIMAL ARCHITECTURAL DESIGN OF PARALLEL AND HYBRID MANIPULATORS M.S. Thesis

Kenneth H. Pittens 1992 175 p
(ISBN-0-315-84351-9; CTN-94-61023) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A study is presented of the optimial design of a class of six degree of freedom (DOF) closed-chain manipulators consisting of serial branches, each with joints acting in parallel on a common end effector. Dexterity measures based on instantaneous kinematic characteristics of the manipulator are used as the primary objective in isolating optimum designs. The fully parallel Stewart platform is first examined and a two-parameter family of optimal configurations is shown to exist. A unique optimum Stewart platform architecture is isolated from those possessing optimum local dexterity. The resulting optimum manipulator architecture is one in which the dimensions of the base are twice those of the platform and the linear actuator attachment points at the base and the platform meet in alternating pairs. Hybrid manipulators are then examined. A specific hybrid chain structure is selected from possible six-DOF structures for further investigation. A class of serial chain branches suitable for this structure is defined and it is shown that only five unique branch structures belong to the kinematically simple class. A novel approach to manipulator configuration optimization for optimal local dexterity objectives is introduced and applied to find optimal configurations of hybrid manipulators utilizing the previously identified branch structures. IMPLEMENTATION OF INTEGRAL MANIFOLD CONTROL ON A TWO DEGREE OF FREEDOM FLEXIBLE JOINT MANIPULATOR: THEORY AND EXPERIMENTS M.S. Thesis
Raymond Wai-Man Tsang 1993 160 p
(ISBN-0-315-83572-9; CTN-94-61039) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Recently, singular perturbation theory and the integral manifold concept were applied to flexible joint modeling. The dynamic model obtained is of the same order as the rigid joint robot and is feedback linearizable with only the joint position and velocity feedback. To verify the feasibility of this approach, an experimental facility was designed and built for the implementation of integral manifold control. The facility consists of a two degree of freedom robot with the distal joint actuated by a 2N tendon-pulley system. A new type of inflatable actuator called a Rubbertuator, developed in Japan, is used in the tendon-pulley system to control the stiffness of the force transmission line. An electronic interface and a system control software which consists of about 8,000 lines of C code were designed. The results of the experimental implementation of the integral manifold control law are reported. These results confirm the published theoretical results and agree with the computer simulation work done by Spong et al. Several limitations of the proposed control are noted. Author (CISTI)

UNSCREENED LOW TENSION CABLES SCRAPE ABRASION TESTING
L. Spilg 1992 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-123767; SP-RAPP-1992:17; ISBN-91-7848-335-2) Avail: CASI HC A03

A proposal for revision of ISO 6722/1--Road vehicles: Unscreened low tension cables, Part 1: General requirements and test methods--specifies a method for scrape abrasion testing. Tests at different laboratories indicate large variations in the results obtained using this method. It is evident that a number of parameters influence the results. In an effort to clarify the influence of some of these parameters, the ISO/TC 22/SC3/WG4-Low Tension Cables decided to undertake an interlaboratory test focusing on different equipment, different conductor types, and different insulating materials. This report presents the method used and the result of the interlaboratory test. It is concluded that it is not possible to compare data obtained on different equipment although they are made according to standard and that further investigations have to be done before including this method in an international standard. AIRCRAFT WHEEL LIFE ASSESSMENT Final Report, 1 Oct. 1991 - 1 Sep. 1992
B. F. Spencer, Jr., D. J. Kirkner, E. E. Schudt, and S. Kandarpa Jul. 1993 62 p
(AD-A274378; WL-TR-93-3065) Avail: CASI HC A04/MF A01

The important part of wheel life assessment problems is the accurate determination of the tire/wheel interface pressure distribution under various loading conditions. A combined analytical/experimental methodology for obtaining this pressure distribution was developed. The principal analytical tool in this methodology is the finite element program ANTWILL (Analysis of Tire Wheel Interface Loads) which recovers the pressure distribution given a number of experimental strain measurements on the wheel. The major activity consisted of a study of the F-16 Block 30 and the Block 40 main landing gear wheels to determine the optimal number and location of the strain gages for subsequent experiments. Experiments to be conducted will record strains at the specified locations and this data will be used to determine tire/wheel interface pressures. DTIC

AN ALGORITHM FOR DETERMINATION OF BEARING HEALTH THROUGH AUTOMATED VIBRATION MONITORING Final Report, 1 Oct. 1992 - 30 Sep. 1993
Sid W. Hite, III Dec. 1993 67 p
(AD-A274591; AEDC-TR-93-19) Avail: CASI HC A04/MF A01

This report investigates considerations involved in designing an expert system capable of real-time monitoring of turbine engine vibration data to detect rolling element bearing faults. Topics include development of the fundamental bearing fault frequencies, data analysis techniques, results of manual analysis, and considerations in bearing health criteria and monitoring. Methodologies are described for characterization of engine family vibration across the engine's envelope, and a bearing health monitoring algorithm is discussed in detail. Work reported will be extended and automated to encompass a complete vibration based turbine engine Health Monitoring System (HEMOS). When completely developed, HEMOS will likely augment the multifaceted capabilities of the Computer Assisted Dynamic Data Monitoring and Analysis System (CADDMAS) under development by the Directorate of Technology - Propulsion Division (DOTP) of Arnold Engineering Development Center (AEDC), Air Force Materiel Command (AFMC), Arnold AFB, TN. COMPUTER SIMULATION AND EXPERIMENTS ON THE QUASI-STATIC MECHANICS AND TRANSPORT PROPERTIES OF GRANULAR MATERIALS Annual Report, 1 Oct. 1992 - 30 Sep. 1993
Xue-Jin Zhuang and J. D. Goddard 1 Oct. 1993 153 p
(Contract F49620-92-J-0037)
(AD-A274192; RR-GR-93-01; AFOSR-93-0912TR) Avail: CASI HC A08/MF A02

This report presents the results of a new quasi-static algorithm developed to compute the mechanical and scalar transport properties of three dimensional sphere assemblages. The algorithm incorporates several new techniques, including a shuffling algorithm for generation of initial random granular packings, an improved microcell-adjacency method to accelerate particle-contact search, and a relaxation method to overcome a singularity in the quasilinear system of equilibrium equations. The calculated Reynolds dilatancy for random dense-packed granular assemblages is found to depend on the interparticle friction, contrary to Reynolds' original hypothesis, and the use of linear contact mechanics is found to be valid near the ideal rigid-particle limit. Triaxial compression tests, employing steel balls as electrically conductive granular particles, confirm the simulation of both mechanical and transport properties, when account is taken of the actual electrical contact resistance between steel balls. The latter is much higher than for Hertzian contact and exhibits a strong dependence on normal load, probably due to asperities and oxide films on the steel-ball surfaces. A major conclusion is that scalar transport can serve as a useful macroscopic probe for stress anisotropy and particle-contact topology in granular media. DTIC

INTERCHANGEABLE END EFFECTOR TOOLS UTILIZED ON THE PFMA Final Report, Sep. 1988 - Jun. 1991
Joe Cody, John Carroll, George Crow, Paul Gierow, Jay Littles, Michael Maness, and Jim Morrison 27 Feb. 1992 44 p
(Contract NAS8-36307)
(NASA-CR-193925; NAS 1.26:193925; SRS/STG-TR92-14; Rept-5490-08) Avail: CASI HC A03/MF A01

An instrumented task board, used for measuring forces applied by the Protoflight Manipulator Arm (PFMA) to the task board, was fabricated and delivered to Marshall Space Flight Center. SRS Technologies phased out the existing IBM compatible data acquisition system, used with a instrumented task board, and integrated the force measuring electronic hardware in with the Macintosh II data acquisition system. The purpose of this change was to acquire all data with the same time tag, allowing easier and more accurate data reduction in addition to real-time graphics. A three-dimensional optical position sensing system for determining the location of the PFMA's end effect or in reference to the center of the instrumented task board was also designed and delivered under. An improved task board was fabricated which included an improved instrumented beam design. The modified design of the task board improved the force/torque measurement system by increasing the sensitivity, reliability, load range and ease of maintenance. A calibration panel for the optical position system was also designed and fabricated. The calibration method developed for the position sensors enhanced the performance of the sensors as well as simplified the installation and calibration procedures required. The modifications made under this effort expanded the capabilities of the task board system. The system developed determines the arm's position relative to the task board and measures the signals to the joints resulting from the operator's control signals in addition to the task board forces. The software and hardware required to calculate and record the position of the PFMA during the performance of tasks with the instrumented task board were defined, designed and delivered to MSFC. PFMA joint input signals can be measured from a breakout box to evaluate the sensitivity or response of the arm operation to control commands. The data processing system provides the capability for post processing of time-history graphics and plots of the PFMA positions, the operator's actions, and the PFMA servo reactions in addition to realtime force and position sensor data presentation. EVALUATING NON-CHLORINATED SOLVENTS FOR WELDING APPLICATIONS

T. M. Mustaleski, Jr., comp. (Martin Marietta Energy Systems, Inc., Oak Ridge, TN.) 11 Aug. 1993 8 p Presented at the 1993 Environmentally Conscious Manufacturing Congress, Arlington, VA, 30 Aug. - 1 Sep. 1993
(Contract DE-AC05-84OR-21400)
(DE94-003332; Y/DV-1275; CONF-93-08150-12) Avail: CASI HC A02/MF A01

There is interest in eliminating the use of chlorinated solvents such as methyl chloroform at the Oak Ridge Y-12 Plant for environmental reasons. Solvent 140 has been offered as an acceptable replacement. Methyl chloroform has frequently been used for the final cleaning of materials just prior to welding. Electron beam welds were made in an aluminum alloy to compare the potential contamination effect of Solvent 140 to that of methyl chloroform. Tests indicated that the Solvent 140 did not have an adverse effect on pump-down time of electron beam welding equipment during normal handling. Solvent 140 resulted in significantly less weld porosity than methyl chloroform in this test. DTIC

SEQUENTIAL MULTI-POINT INJECTION OF A NATURAL GAS ENGINE. TOPICAL REPORT, NOVEMBER 1991 - APRIL 1992

Corwin Snyder and Carina Boschi (Gaz de France, La Plaine Saint Denis.) Apr. 1993 225 p See also PB92-101468 and PB92-123694
(Contract GRI-5086-293-1848)
(PB94-126794; SWRI-3178-4.12; GRI-93/0182) Avail: Issuing Activity (National Technical Information Service (NTIS)

The objective of the project was to evaluate an electronic sequential multi-point injection fuel system on a natural gas-fueled automotive medium-duty engine. This included an evaluation of gaseous fuel injectors, cylinder-to-cylinder fuel-air distribution measurement, performance measurements, exhaust emissions measurements (pre- and post-catalyst), and an oxygen sensor comparison. One additional objective was to run the fuel system in a 'pre-mix' configuration, where fuel and air are mixed for a homogeneous-charge prior to cylinder admission, for comparison to the sequential multi-point fuel system. DESIGN AND EXPERIMENTAL PERFORMANCE OF A TWO STAGE PARTIAL ADMISSION TURBINE. TASK B.1/B.4 Final Report, Dec. 1984 - Jun. 1986

R. F. Sutton, J. L. Boynton, R. A. Akian, Dan Shea, Edmund Roschak, Lou Rojas, Linsey Orr, Linda Davis, Brad King, and Bill Bubel et al 14 Dec. 1992 168 p
(Contract NAS3-23773)
(NASA-CR-179548; NAS 1.26:179548; RI/RD92-214) Avail: CASI HC A08/MF A02

A three-inch mean diameter, two-stage turbine with partial admission in each stage was experimentally investigated over a range of admissions and angular orientations of admission arcs. Three configurations were tested in which first stage admission varied from 37.4 percent (10 of 29 passages open, 5 per side) to 6.9 percent (2 open, 1 per side). Corresponding second stage admissions were 45.2 percent (14 of 31 passages open, 7 per side) and 12.9 percent (4 open, 2 per side). Angular positions of the second stage admission arcs with respect to the first stage varied over a range of 70 degrees. Design and off-design efficiency and flow characteristics for the three configurations are presented. The results indicated that peak efficiency and the corresponding isentropic velocity ratio decreased as the arcs of admission were decreased. Both efficiency and flow characteristics were sensitive to the second stage nozzle orientation angles. Author (revised)

ROBOTICS HANDBOOK. VERSION 1: FOR THE INTERESTED PARTY AND PROFESSIONAL

Dec. 1993 46 p
(NASA-TM-109690; NAS 1.15:109690) Avail: CASI HC A03/MF A01

This publication covers several categories of information about robotics. The first section provides a brief overview of the field of Robotics. The next section provides a reasonably detailed look at the NASA Robotics program. The third section features a listing of companies and organization engaging in robotics or robotic-related activities; followed by a listing of associations involved in the field; followed by a listing of publications and periodicals which cover elements of robotics or related fields. The final section is an abbreviated abstract of referred journal material and other reference material relevant to the technology and science of robotics, including such allied fields as vision perception; three-space axis orientation and measurement systems and associated inertial reference technology and algorithms; and physical and mechanical science and technology related to robotics. OPTIMISING BMW FOUR-CYLINDER TWO-VALVE ENGINES

R. Flierl, F. Kramer, H. Rech, U. Stanski, and M. Wenzel Nov. 1993 35 p
(PB94-125101; MIRA TRANS-93/13) Avail: Issuing Activity (National Technical Information Service (NTIS))

In model year 1994, BMW will present two essentially redesigned 4-cylinder, 2-valve engines. BMW has upgraded its 1.6 1 and 1.8 1 2-valve engines using technical features previously reserved for the 4-valve engines, such as knock control system, distributorless semiconductor ignition, variable induction system (DISA) and ribbed V-belt accessory drive, along with measures to reduce power losses, noise levels and exhaust emissions. BMW models equipped with these two engines offer customers improved response characteristics and fuel consumption, as well as reduced emissions and maintenance requirements. NTIS

GUIDELINES FOR UNLUBRICATED SLIDING WEAR TESTS. PART 1: GENERAL APPROACH
M. G. Gee 1993 16 p
(PB94-119666; NPL-DMM(A)-96-Pt-1) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

This document has been prepared by the author on behalf of the UK Forum on Friction and Wear Testing. The Forum has the overall objectives of improving the reproducibility and repeatability of friction and wear testing in the UK by open discussion and participation in national and international pre-standardization activities. This document serves as a general introduction to friction and wear testing in sliding. It contains a discussion on the most effective approach to friction and wear testing, and it considers the different aspects that should be considered when designing a program of friction and wear testing. GENERALIZED FINITE ELEMENT DYNAMIC MODELLING AND SIMULATION FOR FLEXIBLE ROBOT MANIPULATORS M.S. Thesis
Feng Zhou Jan. 1993 158 p
(ISBN-0-315-84623-2; CTN-94-61079) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The finite element approach is used to model multi-link flexible robotic manipulators. The kinematic character of flexible manipulators is analyzed using body-fixed and link element attached coordinates. Dynamic equations for flexible robot manipulators are then derived. The position of each point on the link is expressed using a transformation matrix, and the kinetic and potential energy for each element is computed and summed over all the elements. The Lagrangian formulation is applied to set up the dynamic equations of the system. Computational simulations are performed on single- and two-link manipulators with and without torque to check the validity and correctness of the derived dynamic equations. The Runge-Kutta method is used to solve the dynamic equations for flexible manipulators on which all the joints are revolute. Author (CISTI)

A robot manipulator is said to be kinematically redundant when it has more degrees of freedom than are necessary to accomplish a particular task. Useful control strategies are designed for kinematically redundant manipulators in order to enhance their performance. Following the impedance control approach, the problem of minimizing redundant manipulator collision impacts is addressed. The configuration control approach is used to reduce impulsive forces, while a simplified impedance control scheme is formulated to minimize rebound effects. A new Cartesian control strategy for redundant flexible-joint manipulators is proposed. The main idea in this hybrid scheme is to control not only the manipulator's end-effector but also its links, so as to achieve specified positions and velocities for the end-effector and the links. Finally, a new application of kinematically redundant manipulators is proposed: using redundancy resolution to compensate for joint flexibility. This redundancy resolution scheme is incorporated in a control strategy for redundant flexible-joint manipulators. The problem of possible algorithmic singularities is considered, and a scheme is suggested which makes the controller robust with respect to such singularities. Author (CISTI)

The results of the studies to solve problems related to manufacturing techniques and calculation methods on externally pressurized porous gas bearings are presented. The following aspects of the studies are outlined: (1) historical backgrounds of studies on the gas lubricated bearings; (2) the machining process of attaining the accuracy required for the gas lubricated bearings; (3) the theoretical analysis on the static performance of this porous gas bearing; (4) the performance under the rotational speed on this type of bearing; and (5) the low-temperature rotating machines for helium refrigerator and the precision measuring instruments with the externally pressurized porous gas bearings which are designed according to the above theoretical and experimental results. ENHANCED SIMULATION SOFTWARE FOR ROCKET TURBOPUMP, TURBULENT, ANNULAR LIQUID SEALS Final Report
Satya Padavala (Texas A&M Univ., College Station.) and Alan Palazzolo (Texas A&M Univ., College Station.) 26 Jan. 1994 291 p
(Grant NAG8-212; TAMU Proj. 41670-ME)
(NASA-CR-195239; NAS 1.26:195239) Avail: CASI HC A13/MF A03

One of the main objectives of this work is to develop a new dynamic analysis for liquid annular seals with arbitrary profile and to analyze a general distorted interstage seal of the space shuttle main engine high pressure oxygen turbopump (SSME-ATD-HPOTP). The dynamic analysis developed is based on a method originally proposed by Nelson and Nguyen. A simpler scheme based on cubic splines is found to be computationally more efficient and has better convergence properties at higher eccentricities. The first order solution of the original analysis is modified by including a more exact solution that takes into account the variation of perturbed variables along the circumference. A new set of equations for dynamic analysis are derived based on this more general model. A unified solution procedure that is valid for both Moody's and Hirs' friction models is presented. Dynamic analysis is developed for three different models: constant properties, variable properties, and thermal effects with variable properties. Arbitrarily varying seal profiles in both axial and circumferential directions are considered. An example case of an elliptical seal with varying degrees of axial curvature is analyzed in detail. A case study based on predicted clearances of an interstage seal of the SSME-ATD-HPOTP is presented. Dynamic coefficients based on external specified load are introduced to analyze seals that support a preload. The other objective of this work is to study the effect of large rotor displacements of SSME-ATD-HPOTP on the dynamics of the annular seal and the resulting transient motion. One task is to identify the magnitude of motion of the rotor about the centered position and establish limits of effectiveness of using current linear models. This task is accomplished by solving the bulk flow model seal governing equations directly for transient seal forces for any given type of motion, including motion with large eccentricities. Based on the above study, an equivalence is established between linearized coefficients based transient motion and the same motion as predicted by the original governing equations. An innovative method is developed to model nonlinearities in an annular seal based on dynamic coefficients computed at various static eccentricities. This method is thoroughly tested for various types of transient motion using bulk flow model results as a benchmark. Derived from text

DEVELOPMENT OF A NEW SEAL FOR USE ON LARGE OPENINGS OF PRESSURIZED SPACECRAFT
B. Weddendorf Mar. 1994 30 p

(Proj. 92-11)
(NASA-TM-108444; NAS 1.15:108444) Avail: CASI HC A03/MF A01

The goal of this project was to design, build, and test an example of the seal invented by the author for use on Space Station Freedom and patented in 1991. The seal features a metallic spring core and replaceable elastomeric sealing elements. The metallic spring is designed to retain the sealing force of the elastomeric element against both sides of face seal gland for any specified amount of waviness or separation of the glands. A seal able to tolerate at least 1.3 mm (0.05 in) of flange distortion or separation and a test fixture of this seal which allowed direct comparison testing of O-rings were built. These designs were tested to compare leakage at different amounts of flange deflection. Results of the testing show the development seal exceeded its requirement to seal 1.3 mm of flange separation by 1 mm. This compared with the O-ring leakage, increasing dramatically at 0.5 mm of separation. The development seal also leaked at a lower rate than the O-ring seals in all tests. Author (revised)

CONTROL OF A HYDROGEN/OXYGEN STEAM GENERATOR [REGELUNG EINES H2/O2-DAMPFERZEUGERS]

Stefan Beer and Herbert Willms Sep. 1992 119 p In GERMAN
(ISSN 0939-2963)
(DLR-FB-93-02; ETN-94-95491) Avail: CASI HC A06/MF A02

An H2/O2 steam generator, which is capable of producing steam at a given thermal capacity and state after a very short period of time, is described. The main components of the system are the reactor and the storage for H2, O2, and H2O. The mathematical model should not be very complex in order to keep the computation time small, but it should be capable of directly describing the main features of the system. Different strategies are proposed for the controller which need different computation times due to their inherent complexity. For the measurement of steam temperature and the ratio of propellant supply, different methods were developed and tested. Results derived from the experimental program are presented and discussed. STREAMWISE VORTICITY IN A TURBINE ROTOR WITH CONICAL ENDWALLS Ph.D. Thesis - Goettingen Univ. [LAENGSWIRBELENTSTEHUNG IM EINEM TURBINENLAUFRAD MIT KONISCHEN SEITENWAENDEN]

Friedrich Kost Apr. 1993 113 p In GERMAN
(ISSN 0939-2963)
(DLR-FB-93-13; ETN-94-95493) Avail: CASI HC A06/MF A02

To investigate the spatial flow structure caused by sweep and dihedral effects in turbomachinery blade rows, detailed measurements were conducted in a windtunnel for rotating annular cascades. The special configuration consisted of a turbine rotor equipped with straight blades, a conical hub, and a conical casing with a cone half angle of 30 deg. Numerous flow data were obtained from surface pressure distributions at seven radial blade sections and from laser velocimetry upstream, downstream, and inside the rotor. It is shown that large deviations from an axisymmetric surface exist in conical flow. The conical flow gives rise to the production of streamwise vorticity which results in increased flow losses. It is furthermore shown that the secondary flow structure is mainly determined by the rotation of the turbine. ESA

DESIGN, IMPLEMENTATION AND EXPERIMENTAL RESULTS OF ROBOTIC ENVIRONMENT INPUT INTO THE ROBOT CONTROLLER TEST STATION (RCTS) M.S. Thesis

Michael A. Ramsay Aug. 1993 192 p
(ISBN-0-315-85355-7; CTN-94-61106) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The Robot Controller Test Station (RCTS) was developed to provide a tool for facilitating the development and integration of robot research for sensor-based robot systems. RCTS software is designed on a modular basis, and each module is a separate entity sharing the same structure as the other modules. Six functional types of modules exist in the original RCTS version and are classified according to whether they perform control or sensing functions. To advance the RCTS system, research was conducted on the inclusion of sensory inputs from the workspace environment surrounding the robot. Such information allows flexible manufacturing control algorithms, multi-robot coordination, and multi-robot avoidance to be tested on the RCTS. The design and implementation of RCTS versions 3 and 4 is described. Version 3 operates on a UNIX-based workstation and a programmable logic controller is used in Version 4 to collect and process information. Implementation of the versions is detailed along with experiments conducted to evaluate RCTS performance. Author (CISTI)

Avail: CASI HC A03/MF A01

A new type of engine seal is being developed to meet the needs of advanced hypersonic engines. A seal braided of emerging high temperature ceramic fibers comprised of a sheath-core construction was selected for study based on its low leakage rates. Flexible, low-leakage, high temperature seals are required to seal the movable engine panels of advanced ramjet-scramjet engines either preventing potentially dangerous leakage into backside engine cavities or limiting the purge coolant flow rates through the seals. To predict the leakage through these flexible, porous seal structures as a function of preload and engine pressures, new analytical flow models are required. An empirical leakage resistance/preload model is proposed to characterize the observed decrease in leakage with increasing preload. Empirically determined compression modulus and preload factor are used to correlate experimental leakage data for a wide range of seal architectures. Good agreement between measured and predicted values are observed over a range of engine pressures and seal preloads. Author

A flexible spherical wrist, susceptible to nonlinear torsional vibrations, was developed which utilizes controllers to provide position control and vibration rejection. The issue of robust performance and stability for this robot wrist is examined while adhearing to practical implementation limits. System identification techniques are used to obtain linear models of the dynamic equations of motion. These models contain physical information such as friction and cable drag, and several different parametric forms are presented. Asymptotic stability of the wrist under proportional derivative control is proven using a linearized set of dynamical equations. Experimental results show only stability rather than asymptotic stability due to friction and unmodeled dynamics. In addition, poor robustness of this control methodology is demonstrated when the orientation and payload are varied. One- and two-parameter Hardy space controllers are designed to address the robustness and implementation issues. Variations in wrist orientation and payload are modeled as multiplicative uncertainties. Simulation and experimental results are presented and compared to those of a tracking controller. The Hardy space controllers are shown to have superior robustness properties but poorer performance. Author (CISTI)

STUDY OF THE KINEMATIC AND DYNAMIC CHARACTERISTICS OF A WORMGEAR TRANSMISSION FOR HELICOPTER APPLICATIONS Final Report

D. C. Sun and Qin Yuan Mar. 1994 138 p
(Grant NAG3-1316; DA Proj. 1L1-61102-AH-45; RTOP 505-62-0K-00)
(NASA-CR-195287; E-8633; NAS 1.26:195287; ARL-CR-78) Avail: CASI HC A07/MF A02

The first phase of the study of the performance of a wormgear transmission is reported. In this phase the work included the selection of a double-enveloping wormgear type, and its dimensions, suitable for use in helicopter transmissions; the 3-D graphics representation of the selected wormgear using the I-DEAS software; the analysis of the kinematics of meshing; the analysis of load sharing among the meshing teeth; and the implementation of the analyses in a computer program. The report describes the analyses, their results, and the use of the computer programs. Author

USING FERRO-MAGNETIC FLUIDS TO LUBRICATE NON-CONFORMAL ISOTHERMAL CONTACTS Ph.D. Thesis - Cranfield Inst. of Technology, 1992
Petronio Noronha deSouza 1993 204 p
(INPE-5520-TAE/021) Avail: CASI HC A10/MF A03

Magnetic fluids are synthetic materials that combine in a single medium the properties of fluids and magnetic materials. The action of a magnetic field on the magnetic fluid allows the design of new types of bearings and also provides conventional ones with new properties. This work presents a contribution to the study of the lubrication of linear isothermal non-conformal contacts with magnetic fluids under the action of a nonuniform magnetic field perpendicular to the plane of the contact. The fluid is assumed to present extrinsic superparamagnetism. The regime of lubrication considered is the isoviscous-rigid. The analytical approach adopted considers small perturbations of the classical analytical solution already known for this type of contact. The main objectives of the work are: to establish the equations and assumptions that are necessary to treat the proposed lubrication problem; to analyze the impact of the change in the apparent viscosity of the magnetic fluid on the thickness of the lubricating film due to the presence of the magnetic field; and to develop an experimental technique able to deal with the problems that arise with the use of magnetic fluids in the lubrication of a two-disc machine. The mathematical treatment of the proposed problem brings together the analytical methods adopted in fluid film lubrication to the analysis of long isothermal hydrodynamic bearings and those from the magnetic-liquid fluid dynamics (ferrohydrodynamics) usually adopted to study the flow of magnetic fluids that present extrinsic superparamagnetism. The result is a coherent system of equations supported by a well defined set of assumptions. The solution obtained allows the study of the eventual change of the film thickness that can be achieved by the application of a magnetic field across the contact. The work also discusses the experimental technique necessary to study the problem in a two-disc machine that runs with minute amounts of lubricant, applies a magnetic field across the contact and measures the film thickness by a capacitance method. The work concludes by showing theoretically that the film thickness can be either increased or reduced depending on the magnetic and viscous properties of the fluid and the intensity of the magnetic field. These conclusions are supported by experiments with a magnetic oil in a two-disc machine. Author

Two independent models of the dynamics of a Schilling Titan II hydraulic manipulator were developed and compared in order to obtain an accurate model of the manipulator dynamics. These models will be used in the development of feedback control laws and active damping algorithms. One of the models is an analytical model which was developed 'by hand' with the assistance of computer symbolic manipulation. The other is a numerical model developed using a commercially available dynamics code. The data from these models were then compared with experimental data from an actual Titan II manipulator. DOE

The basic concept thus derived from the Ericsson cycle is an intercooled, recuperated, and reheated gas turbine. Theoretical performance analyses, however, showed that reheat at high turbine rotor inlet temperatures (TRIT) did not provide significant efficiency gains and that the 50 percent efficiency goal could be met without reheat. Based upon these findings, the engine concept adopted as a starting point for the gas-fired advanced turbine system is an intercooled, recuperated (ICR) gas turbine. It was found that, at inlet temperatures greater than 2450 F, the thermal efficiency could be maintained above 50%, provided that the turbine cooling flows could be reduced to 7% of the main air flow or lower. This dual and conflicting requirement of increased temperatures and reduced cooling will probably force the abandonment of traditional air cooled turbine parts. Thus, the use of either ceramic materials or non-air cooling fluids has to be considered for the turbine nozzle guide vanes and turbine blades. The use of ceramic components for the proposed engine system is generally preferred because of the potential growth to higher temperatures that is available with such materials. DOE

(Contracts DEN3-374; DE-A101-91CE-50306)
(NASA-CR-187158; NAS 1.26:187158; DOE/NASA/0374-1) Avail: CASI HC A05/MF A01

Analysis and concept design work completed in Phase 1 have identified a low heat rejection engine configuration with the potential to meet the Heavy Duty Transport Technology program specific fuel consumption goal of 152 g/kW-hr. The proposed engine configuration incorporates low heat rejection, in-cylinder components designed for operation at 24 MPa peak cylinder pressure. Water cooling is eliminated by selective oil cooling of the components. A high temperature lubricant will be required due to increased in-cylinder operating temperatures. A two-stage turbocharger air system with intercooling and aftercooling was selected to meet engine boost and BMEP requirements. A turbocompound turbine stage is incorporated for exhaust energy recovery. The concept engine cost was estimated to be 43 percent higher compared to a Caterpillar 3176 engine. The higher initial engine cost is predicted to be offset by reduced operating costs due the lower fuel consumption. Author (revised)

A NEW METHOD FOR TORSIONAL CRITICAL SPEED CALCULATION OF PRACTICAL INDUSTRIAL ROTORS
Oh-Sung Jun and Paul Y. Kim (National Research Council of Canada, Vancouver, British Columbia.) Jul. 1993 78 p
(IMR-T&M-TR-001; CTN-94-61010) Avail: CASI HC A05/MF A01

A new approach to calculating the torsional critical speed of rotors is presented. The governing equations for these speeds and the method of solutions differ from existing methods such as Holzer's, and the theory and numerical algorithm are straight forward, without any change in the field variables. The rotor studied has a distributed mass and rigid disks, and consists of many shaft segments of different diameters. The exact solution for undamped torsional motion of a uniform shaft segment is applied to a practical rotor-bearing system to generate the simultaneous governing equations for the torsional critical speeds. Within the framework of the theory, the set of governing equations is completely analytical and explicit, and it does not include any approximations, such as discretization of shaft mass and polynomial approximations. A computer program for the torsional critical speeds and the related mode shapes is developed by introducing a simple recurring numerical algorithm for a 3 by 4 submatrix in calculating the determinant generated by the simultaneous equations. The numerical algorithm essentially eliminates the necessity of constructing a huge matrix. The effectiveness of the new method is demonstrated in analyses of three rotors. Author (CISTI)

Information and data that are intended to provide an in depth understanding of gas turbine engine transient behavior, the modeling methods that are applied to transient events, and the simulation technology that supports the transient analysis process are presented. The diverse nature of the disciplines that are applied to the study of transient behavior makes it necessary to examine the subject from at least three perspectives: the application of the underlying technology to specific design and development concerns; the development of the mathematical models that support the various applications; and the computer programs that implement the models and provide the analytical capability required by the different applications. For individual titles, see N94-28044 through N94-28054.

A set of graphics with explanations illustrating gas turbine engine steady state behavior are presented. Typical combinations of compressors and nozzles which occur in a gas turbine engine are shown. The basic effect of a nozzle is explained by considering a compressor on a test rig: typical compressor, fan, and turbine characteristics are illustrated. The following are discussed: the degrees of freedom of an aeroengine (the flow and the power); the 'working lines' of components (the locus of the off design steady state operating points of a component plotted on a chart of that components characteristics); bleed and whirl; offtakes; P1 effects (performance changes which modify the basic nondimensional behavior an engine (caused by the effect on Reynolds number levels and on engine mechanical configuration of basic engine inlet pressure level)), and T1 effects (performance changes which modify the basic nondimensional behavior of an engine and are caused by the effects of engine inlet temperature level on Reynolds number level, on engine mechanical configuration and on specific heat level); variable nozzles; and turbojet matching. TRANSIENT PERFORMANCE
Barry Curnock *In* VKI, Gas Turbine Engine Transient Behaviour 1993 32 p (For primary document see N94-28043 07-37)
Copyright Avail: CASI HC A03/MF A03

Gas turbine engine transient behavior, that which is concerned with the changes in engine parameters during acceleration or decceleration of an engine from one steady state point to a different steady state point, is considered. An engine can also experience cyclic aerodynamic phenomena which occur at a nominally steady condition; examples are compressor rotator stall and intake or afterburner buzz. The following are discussed: certification requirements; mechanism of acceleration; compressor working lines and surge; and some important factors (pressure level, moment of inertia, heat soakage, clearances, measurement of transients, thrust reversal, and transient maneuvers which involve significant changes to the shaft speeds of the engine). A set of graphics illustrating transient performance is presented. ESA

COMPRESSOR STABILITY
Barry Curnock *In* VKI, Gas Turbine Engine Transient Behaviour 1993 29 p (For primary document see N94-28043 07-37)
Copyright Avail: CASI HC A03/MF A03

Various operating modes and conditions of the gas turbine which may cause compressor stall are considered. The behavior of a compressor in stall is explained because the engineer, although designing to avoid stall, must consider the possibility of stall and what control measures must be taken to recover engine operability. A major cause of stall is inlet distortion, that is a nonuniform pressure and/or temperature profile at entry to the compressor. The causes and effects of distortion are discussed. A set of graphics illustrating the above is also presented. ESA

N94-28047# Rolls-Royce Ltd., Derby (England).
ENGINE STARTING AND STOPPING

Different starter systems for jet engines are discussed: electric, cartridge, iso-propyl-nitrate, air, gas turbine, and hydraulic. The fuel system, ignition system, air flow control system, and actual starting mechanism of an air starter motor system are considered. The variation of engine parameters throughout a typical starting sequence are described, with reference to examples for an RB211-535 engine. Physical constraints on engine starting are considered: rotating stall, light up, the window between hang and stall, hang, compressor stall, and the effects of ambient conditions. The following are also discussed: contractual and airworthiness requirements; windmilling; inflight relighting; afterburning light up; combustion stability; and broken shafts. Graphics illustrating the above are presented. ESA

One of the potentially many ways in which expanding the objectives, requirements, and capabilities of engine simulation might improve the cost and time effectiveness of the engineering process in aircraft engine design is examined. The engine simulation developed for the analysis of heat soak and clearance effects on compressor performance and stability required technology interactions between heat transfer, mechanical design, and compressor aerodynamics. The objective and requirements of the models provided by the interacting technical disciplines were limited to the objectives of determining the compressors internal flow path heat transfer rates and clearances and the effect of these on the compressor performance and stability. The compressor aerodynamics model computes the performance of each compressor stage both at the stall line and the operating line with and without the stage heat addition and clearance variation. Boundary conditions for the aerodynamics model are required from the engine model as well as from the heat transfer and clearance models. ESA

A series of stall capable models which support the engine operability design effort for variable cycle engines is discussed. These models were derived from existing transient simulations which included the control, sensor, and actuator models. The process of constructing the stall models was accomplished in two steps. The first step was the addition of volume dynamics elements throughout the engine simulation. The core and bypass flows were partitioned into several volumes and the compression components were defined as sources and sinks of mass, momentum and energy at boundaries of these volumes. The second step was the extension of compression component performance representations to include in-stall operation. The methods used to accomplish these steps are illustrated with a simple model of a compressor test rig. Graphs showing the variation of compressor power, compressor momentum capability and system response and inlet corrected speed during a repeatable surge cycle and simulation are presented. The compressor inlet and exit pressure, the air flow and the temperature response during surge cycle simulation are graphically illustrated. In-stall and unstalled performance and efficiency are graphically illustrated at 70 to 75% corrected speed, and at 50 and 60% corrected speed. The temperature and momentum variation during a nonrecoverable stall simulation are also graphically illustrated. All graphs are discussed. ESA

TRANSIENT MODEL APPLICATIONS. 3: TRANSIENT ENGINE SIMULATION AND ANALYSIS OF AN ICE INGESTION TEST
Peter W. McDonald *In* VKI, Gas Turbine Engine Transient Behaviour 1993 15 p (For primary document see N94-28043 07-37)
Copyright Avail: CASI HC A03/MF A03

A transient engine model capable of simulating the transient response of an aircraft engine ice ingestion is examined. This model is required to simulate a controlled test which would provide data with which the model could be verified. Ice ingestion testing is routinely conducted with the objective of demonstrating the ability of an aircraft engine to safely operate while an aircraft passes through a hail storm. The most critical test condition is at a flight idle power setting where the engine power is low (or the capability to melt ice and evaporate water is limited) and the concentration of hail relative to the engine inlet airflow is high. The ice ingestion test was accomplished with a set of ice guns which shot large quantities of uniformly distributed ice at the fan hub region (into the core of the engine). The ice was crushed and filtered to match the size of hail stones and fired at a velocity consistent with the air speed being represented by the test. The response of certain engine parameters, as predicted by the model, to the ice ingestion test, is graphically illustrated and discussed. Examples include fuel flow, fan speed, core speed, compressor discharge pressure, compressor discharge temperature. ESA

NONLINEAR SOLVERS
Peter McLaughlin *In* VKI, Gas Turbine Engine Transient Behaviour 1993 10 p (For primary document see N94-28043 07-37)
Copyright Avail: CASI HC A02/MF A03

A typical example of a nonlinear solver used in several different engine simulation programs is described, including its interaction with the dynamic and discontinuous aspects of the model. The model equations are solved using the Newton-Raphson technique augmented by a matrix update based on Broyden's method. This solver is applied in both transient and steady state cases and provides reliable convergence of the set of implicit relationships required by the model. Broyden's method provides efficient convergence on component based engine models operating in the normal power range. However, several computations in a quasi Newton Broyden solver utilizing normalized parameters become indeterminate when the iteration variables, for example rotor speeds and flows, approach zero during starting or shutdown. REPLICAS (Rational, Effective Procedures and Logic for the Implementation of Computerized Analysis and Simulation), is a collection of algorithms that is intended to provide convergence properties that are independent of the magnitudes of the iteration variables. In REPLICAS, a unique algorithm is employed which automatically provides an additive bias on the iteration variable. This bias is chosen in such a way as to maintain the magnitudes of the matrix elements at relatively constant values, independent of the absolute magnitude of the actual iteration variables. ESA

CONTACT STRESS IN DISC CAMS WITH ROLLER FOLLOWERS
Mar. 1993 48 p
(ISSN 0141-4046)
(ESDU-93001; ISBN-0-85679-843-6) Avail: ESDU

ESDU 93001 presents a Fortran program that calculates the compressive stress in the contact region of a barrelled roller translating (radial or offset) or swinging arm follower at 1 degree intervals during the cam cycle. Also output are the dimensions of the contact zone and the decrease in separation of the cam and the roller centers. The method applies to unlubricated surfaces or situations where the lubrication regime is elastohydrodynamic or boundary. The method calculates the force at the cam/roller interface due to follower system inertia, action of the return spring and the externally applied load which can be specified at 1 degree intervals of cam rotation, at a few points, or by a sine function. Six cam laws are treated but an option is provided for a user-specified law to be input. The values of contact force, together with cam profile radius of curvature, roller dimensions, and Young's modulus and Poisson's ratio of the cam and roller materials are used to calculate the contact stress following the method of ESDU 78035. An option is included to determine suitable values of spring rate and preload to ensure that contact between cam and follower is maintained. A description of the mathematical model programmed is provided together with guidance on the use of the program, a full description of the input and output formats illustrated by three realistic worked examples, and an explanation of warning messages that may be generated. The program, ESDUpac A9301, is provided on disc (uncompiled) in the software volume and also compiled within ESDUview, a user-friendly shell running under MS DOS that prompts on screen for the input data. ESDU

BLENDING PROFILES OF DISC CAMS WITH RADIAL TRANSLATING ROLLER FOLLOWERS. PART 2: TO INCORPORATE AN INTERMEDIATE PRECISION POINT OR A CONSTANT VELOCITY COMPONENT
Sep. 1993 47 p
(ISSN 0141-4046)
(ESDU-93002-Pt-2; ISBN-0-85679-844-4) Avail: ESDU

ESDU 93002 uses a method by which each motion segment (rise or return) is formed by blending together components of two single-law segments at the point of maximum follower velocity. A hand calculation method may be used, based on the graphs of ESDU 92005 relating to six commonly-used cam laws, or Fortran programs (ESDUpac A9302 for the precision point and ESDUpac B9302 for the constant velocity component), and both techniques yield the minimum allowable size of cam (based on the requirements that the maximum pressure angle does not exceed a specified value and that profile undercutting is avoided). The program also uses the six common cam laws but a user-specified law may also be input provided the maximum velocity occurs at the mid-point of a single segment. The output from the programs can if required include the follower motion at 1 degree intervals for a full cam rotation (displacement, velocity, acceleration and jerk). The theoretical background to the method is explained, step-by-step design procedures are detailed, and guidance on the use of the programs is given. A full description of the input and output formats is illustrated by practical worked examples. The programs are provided on disc (uncompiled) in the software volume and also compiled within ESDUview, a user-friendly shell running under MS DOS that prompts on screen for input data. ESDU 83027 also provides a hand calculation method for blending that applies to both translating and swinging arm followers but provides no information on minimum cam size. ESDU

CALCULATION METHODS FOR STEADILY LOADED CENTRAL CIRCUMFERENTIAL GROOVE HYDRODYNAMIC JOURNAL BEARINGS (GUIDE TO USE OF COMPUTER PROGRAM A9304)
Aug. 1993 25 p
(ISSN 0141-2590)
(ESDU-93004; ISBN-0-85679-856-8) Avail: ESDU

ESDU 93004 introduces a Fortran program that implements the calculation method of ESDU 90027. The program predicts the minimum lubricant film thickness (taking any misalignment into account), eccentricity ratio, the power loss, the lubricant flow rate, and the bearing and lubricant temperatures. It can, optionally, provide a preliminary design to satisfy specified requirements and constraints. The preliminary design method incorporates recommendations for lubricant grade and feed pressure, bearing overall size and proportions, running clearance, and groove dimensions. The program applies for any liquid acting as a lubricant that can be regarded as Newtonian and lubricant properties are held in a database that can be edited or to which further lubricants may be added. The program provides warnings if the bearing temperature is too high, the outlet temperature is too high, the lubricant temperature is outside the usable range, the film thickness is too small, or if there is a risk of half-speed whirl. Suggestions for remedial action in each case are made. The input and output format is fully explained and illustrated with worked examples. The program is available on disc (uncompiled) in the software volume as ESDUpac A9304. ESDU

Papers which aim to provide an in depth understanding of the principles and practices of combined cycle power generating systems are presented. The increased use of natural gas and the development of clean coal technology has led to a renewed interest in combined cycles to maximize plant efficiency. The fundamentals of cycle thermodynamics and the design of plant components are covered, with particular reference to the design of industrial gas turbines and the associated steam plant and heat rejection system. Plant control and monitoring, methods of reducing emissions, and measurement of performance are also included. Plants fired by natural gas and developments of combined cycles for clean coal combustion systems such as fluidized beds and integrated gasification systems are addressed. For individual titles, see N94-28078 through N94-28090.

Copyright Avail: CASI HC A03/MF A04

Ideas and concepts underlying the technology of combined cycles including the scientific principles involved and the reasons these cycles are in fashion at the present time, are presented. A cycle is a steady flow process for conversion of heat energy into work, in which a working medium passes through a range of states, returning to its original state. Cycles for power production are the steam cycle, which is a closed cycle, and the gas turbine, which represents an open cycle. Combined cycle thermodynamic parameters, are discussed. The general arrangement of the plant is outlined and important features of their component parts described. The scope for future development is discussed. It is concluded that for the next few years the natural gas fired combined cycle will be the main type of plant installed for electricity generation and cogeneration. Whilst gas turbines may not increase substantially in unit size, there remains scope for further increase in firing temperature with consequent increase in cycle performance. However the larger global reserves of coal are providing an incentive to the development of plant for clean coal combustion using the inherent advantage of the combined cycle to attain high efficiencies. Copyright Avail: CASI HC A04/MF A04

The fundamental thermodynamics of power plants including definitions of performance criteria and an introduction to exergy are reviewed, and treatments of simplified performance calculations for the components which form the major building blocks and a gas/steam combined cycle plant are given: the gas turbine, the heat recovery steam generator, and the remainder of the steam plant. Efficiency relationships and energy and exergy analyses of combined cycle plant are presented, with examples. Among the aspects considered are gas turbine performance characteristics and fuels, temperature differences for heat recovery, multiple steam pressures and reheat, supplementary firing and feed water heating. Attention is drawn to points of thermodynamic interest arising from applications of combined cycle plant to repowering of existing steam plant and to combined heat and power (cogeneration); some advances, including coal firing, are also introduced. DEVELOPMENT OF THE GAS TURBINE. PART 1: DESIGN PHILOSOPHY AND PERFORMANCE
Leroy O. Tomlinson *In* VKI, Combined Cycles for Power Plants 1993 65 p (For primary document see N94-28077 07-37)
Copyright Avail: CASI HC A04/MF A04

The development of the gas turbine from its conception in the 1930's up until present day is outlined. Focus is on the industrial gas turbines which were designed specifically for large combined cycle power generation applications. The materials used, which have to be cost effective, reliable, and have a long life, are discussed. The gas turbine controls, which have almost universally developed to a computer based system to perform control logic sequencing and protective logic, are also considered. The information given includes development, in firing temperature, compressor pressure ratio, efficiency, NO(x) emission, and compressor air flow. ESA

N94-28081# General Electric Co., Schenectady, NY.
DEVELOPMENT OF THE GAS TURBINE. PART 2: MANUFACTURING, COMMISSIONING, AND OPERATION
Leroy O. Tomlinson *In* VKI, Combined Cycles for Power Plants 1993 42 p (For primary document see N94-28077 07-37)

Major accomplishments in the development of gas turbine manufacturing are considered including the important manufacture of high temperature turbine buckets by precision casting. Other developments considered are as follows: directional solidification, applications of coatings in a vacuum, forging, quality checks, and casings. The factory packaging of gas turbines and their accessories, which simplifies and speeds field installation, is considered. The economic power generation cost is also considered. The elements of power generation cost include the fixed charges that are usually a fixed fraction of the installed cost, fuel, operation, and maintenance. The ways in which these elements are influenced by the design of the equipment are discussed. ESA

Parameters affecting steam turbines design are discussed and it is concluded that steam turbines for combined cycles are suitable for: powers between 1 and 250 MW; driving a generator, via a gearbox if necessary; drive through of powers which can be up to three times their own power; and ground level installation with up, side, or axial exhaust for condensing turbine applications. Parameters affecting the steam turbine performance are discussed: inlet conditions and flows, sliding inlet conditions, reheat cycles, fired and unfired heat recovery steam generators, cogeneration systems, and combined cycle for process steam supply. Aerodynamic design aspects of steam turbines for combined cycles are discussed. It is concluded that steam turbines for combined cycles have a large range of special requirements. Some typical aspects are: large exhaust annular areas and special exhaust arrangements for condensing steam turbines, drive through of the power of the gas turbines, high influence on the total cycle performance optimization, and a wide variety of extraction systems for cogeneration. COOLING TOWERS FOR COMBINED CYCLES: NEW DEVELOPMENTS TO MEET ENVIRONMENTAL REQUIREMENTS
M. Vouche, F. Bouton (Hamon-Sobelco, Belgium.), and P. Lemmens (Hamon-Sobelco, Belgium.) *In* VKI, Combined Cycles for Power Plants 1993 43 p (For primary document see N94-28077 07-37)
Copyright Avail: CASI HC A03/MF A04

Two new developments in dry cooling systems are presented: the single row condenser (SRC) finned tube and the natural draft air-cooled condenser (NDC). The SRC tube is a flat finned tube based on a technology used for compact heat exchangers. This tube was specifically developed for vacuum air-cooled condensers. The serpentine fins of the SRC tube could be made in aluminum or in galvanized steel. The special technique of the brazing of the aluminum fins is described. A technical and economical comparison is made between the classical dry cooling equipment and the NDC. This comparison concludes with the high economic interest in combining the NDC and the single row design. The mechanical draught wet cooling towers with plume abatement are introduced and compared to classical parallel hybrid and reduced plume towers. The environmental impact of wet cooling towers is discussed with regard to heat and mass transfer, plume, bulkiness, and noise. ESA

CLEAN COAL TECHNOLOGY
P. C. Richards, J.-B. Wijffels, and P. L. Zuideveld *In* VKI, Combined Cycles for Power Plants 1993 24 p (For primary document see N94-28077 07-37)
Copyright Avail: CASI HC A03/MF A04

The different commercially available clean coal technologies are introduced with particular emphasis on their efficiency and environmental performance. The technologies in question are: pulverized fuel combustion with flue gas desulphurization; circulating fluidized bed combustion; integrated coal gasification combined cycle; pressurized fluidized bed combustion. Consideration is also be given to emerging coal combustion technologies. ESA

INTEGRATED COAL GASIFICATION COMBINED CYCLE
P. C. Richards, J.-B. Wijffels, and P. L. Zuideveld *In* VKI, Combined Cycles for Power Plants 1993 26 p (For primary document see N94-28077 07-37)
Copyright Avail: CASI HC A03/MF A04

Features of the integrated coal gasification combined cycle power plants are described against the backdrop of the development and first commercial application of the shell coal gasification process. Focus is on the efficiency and excellent environmental performance of the integrated coal gasification combined power plants. Current IGCC projects are given together with an outline of some of the options for integrating coal gasification with combined cycles and also other applications of synthesis gas. ESA

EJECTORS AND JET PUMPS: COMPUTER PROGRAM FOR DESIGN AND PERFORMANCE FOR LIQUID FLOW
Dec. 1993 50 p
(ISSN 0141-4011)
(ESDU-93022; ISBN-0-85679-875-4) Avail: ESDU

ESDU 93022 introduces a Fortran program (ESDUpac A9322) for ejectors in which the primary and secondary flows are of non-reacting miscible liquids. Inlet conditions for both primary and secondary flows can be either constant pressure or provided by a pump. In the latter case it is assumed that the head can be expressed as a quadratic in pump speed and flow rate. Two procedures are provided: a Design Procedure and Performance Prediction. For the first the input is a selection of entry and required exit pressures and flow rates, together with estimates of loss coefficients in the primary and secondary nozzles, mixing duct and diffuser. The program will optimize the ejector, calculating the primary nozzle, secondary inlet and ejector exit dimensions. For the second case, the ejector dimensions are input together with the loss factors again and a range of entry flow conditions and the program will calculate flow conditions throughout the ejector and at exit. The equations on which the program is based are fully specified, the input format required is set out in clear tables, and two worked examples illustrate the use of both procedures. The program is provided on disc (uncompiled) in the software volume, and compiled within ESDUview, a user-friendly shell running under MS-DOS that prompts on screen for input data. ESDU

(ISVR-TR-228) Copyright Avail: Issuing Activity (Inst. of Sound and Vibration Research, Univ. of Southamapton, Southampton SO9 5NH, England)

The sensitivity to small physical changes of the vibrational response of a mechanical system to external excitation increases with frequency. In time-stationary vibration, with conservative coupling, Statistical Energy Analysis (SEA) aims at providing a reliable tool not only to assess the gross distribution of energy within a system but also to give an idea of this distribution among quasi-similar systems. ADVANCED METALLIC EXHAUST IMPINGED STRUCTURAL CONCEPTS DEMONSTRATION Interim Technical Report No. 2, 7 Nov. 1992 - 5 May 1993
J. W. Bohlen, M. T. Hahn, and J. O. Bunch Jun. 1993 110 p
(Contract F33615-92-C-3201)
Avail: CASI HC A06/MF A02

The goal of the program is to design, develop, and test an advanced metallic exhaust impinged structure. The technology developed will provide a generic solution that can be applied to future advanced aircraft. Phase 1 preliminary design was initiated for two film-cooled concepts using either slots or small holes (transpiration cooling). Both designs were based on the same loft lines, loading requirements, and thermal/pressure profiles (from computational fluid dynamics). Finite element, dynamic, and thermal analyses were begun for the designs and for an uncooled baseline design. The functionality and scalability of the designs were assessed. Preliminary design testing of the candidate structural materials was begun. Author (revised)

UPSET WELDING PROCESS FOR 21-6-9 SPHERICAL VESSELS

W. R. Kanne, Jr. Feb. 1993 16 p
(Contract DE-AC09-89SR-18035)
(DE93-018194; WSRC-TR-93-015) Avail: CASI HC A03/MF A01

An upset resistance welding process which was developed to fabricate high quality spherical vessels from forged 21-6-9 stainless steel is discussed. The two hemishells of the vessels were joined at the girth using solid-state upset welding. Vessels passed nondestructive examinations (X-ray radiography, proof and leak tests, volume and dimensional measurements) and destructive examinations (burst tests and metallography). A set of six high quality vessels was produced. These vessels are 1.86 inches in diameter with a threaded boss and tube on top. DOE

SPACE SHUTTLE MAIN ENGINE TURBOPUMP BEARING ASSESSMENT PROGRAM
B. Spiegel Breithaupt Mar. 1994 39 p
(NASA-TM-108447; NAS 1.15:108447) Avail: CASI HC A03/MF A01

This report documents the work done on the bearing assessment program over the past two and a half years. The objective of the program is to develop a nondestructive evaluation system for the SSME HPOTP's which would be used to detect anomalies in installed bearings without engine disassembly. Data bases of various signatures are obtained by slowly turning the pump shafts before and after an engine firing. These signatures are then analyzed and compared to the original signatures to more accurately predict bearing wear. Author (revised)

This report is the result of a study to evaluate two procedures in MIL-STD-883D, Test Method 1014.9 (Seal) and Test method 1018.2 (Internal Water-Vapor Content). The first portion of this report reviews and investigates the current test procedures included in Test Method 1014 and explores new test methods for recommendation of incorporation into a new revision of the test method. Included in Appendix-B are the results of a survey of industry for comments and recommendations for improving and clarifying the present test method. Appendix A of this report presents the proposed new version of Test Method 1014. The second portion of this report details the results of a study that provided and distributed Test Method 1018 moisture measurement correlation samples to various Residual Gas Analysis (RGA) laboratories. This was done in order to determine the accuracy and precision of mass spectrometric measurement of moisture in microelectronics packages at facilities deemed suitable or candidates to be deemed suitable by the Defense Electronic Supply Center (DESC) to perform MIL-STD-883D, Test Method 1018.2, Procedure 1 (Mass Spectrometry), moisture testing. AN EXPLORATORY SURVEY OF METHODS USED TO DEVELOP MEASURES OF PERFORMANCE M.S. Thesis
Kenneth L. Hamner and Charles A. LaFleur Sep. 1993 111 p
(AD-A273945; AFIT/GSM/LAS/93S-6) Avail: CASI HC A06/MF A02

Nonmanufacturing organizations are being challenged to provide high-quality products and services to their customers, with an emphasis on continuous process improvement. Measures of performance, referred to as metrics, can be used to foster process improvement. The application of performance measurement to nonmanufacturing processes can be very difficult. This research explored methods used to develop metrics in nonmanufacturing organizations. Several methods were formally defined in the literature, and the researchers used a two-step screening process to determine the OMB Generic Method was most likely to produce high-quality metrics. The OMB Generic Method was then used to develop metrics. A few other metric development methods were found in use at nonmanufacturing organizations. The researchers interviewed participants in metric development efforts to determine their satisfaction and to have them identify the strengths and weaknesses of, and recommended improvements to, the metric development methods used. Analysis of participants' responses allowed the researchers to identify the key components of a sound metrics development method. Those components were incorporated into a proposed metric development method that was based on the OMB Generic Method, and should be more likely to produce high-quality metrics that will result in continuous process improvement. HIERARCHICAL TEST DEVELOPMENT AND DESIGN-FOR-TESTABILITY FOR (A)SYNCHRONOUS SEMI-CUSTOM ASIC'S Ph.D. Thesis
Jentje Leenstra 1993 207 p
(ISBN-9-09-005928-8; ETN-94-95343) Copyright Avail: CASI HC A10/MF A03

The work is concerned with test program development and with design for test techniques for low volume semi custom Application Specific Integrated Circuits (ASIC's). Semi custom ASIC design and the growing problems in test development are discussed. The test development problems are growing due to the increasing complexity of the semi custom ASIC's and the need to reach 100% fault coverage in safety critical applications. The design for test techniques and associated automated test development approaches are presented. Test application costs for semi custom ASIC's are considered. Integrated design and test development are discussed. A Design For Testability (DFT) technique for the design of scan testable (a)synchronous control circuits and dedicated test development techniques for purely synchronous circuits parts are presented. STATISTICAL QUALITY MANAGEMENT
Paul vanderLaan Oct. 1992 17 p In DUTCH Presented at GEWIS voor Wiskunde en Informatica Lecture, Eindhoven, Netherlands, 21 Oct. 1992
(ISSN 0926-4493)
(MEMO-COSOR-92-43; ETN-94-94804) Avail: CASI HC A03/MF A01

Some aspects of statistical quality management are discussed. Quality has to be defined as a concrete, measurable quantity. The concepts of Total Quality Management (TQM), Statistical Process Control (SPC), and inspection are explained. In most cases SPC is better than inspection. It can be concluded that statistics has great possibilities in the field of TQM. ESA

AN APPROACH TO STUDYING THE RELIABILITY OF MICROGRAVITY EXPERIMENTS
Michael Thaggard (Science Applications International Corp., Brook Park, OH.) and Daniel P. Morilak Mar. 1994 14 p Presented at the Aerospace Design Conference, Irvine, CA, 16-19 Feb. 1993; sponsored by AIAA, AHS, and ASEE See also A93-30937
(Contract NAS3-25515; RTOP 323-42-04)
(NASA-TM-106489; E-8476; NAS 1.15:106489) Avail: CASI HC A03/MF A01

The identification of key factors that influence the nonsuccess of experiments conducted under microgravity conditions will aid in the planning, design, and implementation of future space shuttle experiments, as well as other microgravity experiments (i.e., experiments conducted on the space station). Similarly, knowledge of the experiments' reliability will assist in forecasting the success of forthcoming experiments. Since a relatively large number of space shuttle experiments have been conducted to date, a substantial pool of data exists for assessing the possible causes or factors which influence experiment nonsuccesses. This report details the task being undertaken at NASA Lewis Research Center (LeRC) to measure the space shuttle experiments' nonsuccess trends and identify causes that significantly affect their performance. It addresses the activities associated with correlating experiment macro-factors with experiment nonsuccesses. The development and implementation of a microgravity database to be used for tracking and correlating experiment nonsuccess factors, as well as the criteria for measuring experiment success and nonsuccess, are also discussed. DEVELOPMENT OF NON-DESTRUCTIVE TESTING TECHNOLOGY FOR THE CRACK OF STEAM GENERATOR TUBES
Yong Moo Cheong, Tae Eon Chung, Chang Jae Yim, and Ki Won Kang Jan. 1993 56 p In KOREAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE93-632953; KAERI/RR-1183/92) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

The artificial defects of slot type with width of 0.2 mm were manufactured by EDM to simulate the axial and the circumferential cracks located at the region of expansion transition of the steam generator tubes. The defect signals of ECT using MRPC were analyzed. It is possible to suppress satisfactorily the malign effects of the variation of the geometry of the tubes on the inspection of cracks by using the MRPC probe. The optimum exciting frequency for the detection of cracks by MRPC is greater than 200 kHz and is less than 400 kHz. The direction of crack has little effect on the detectability of the defect. DOE

A COMPARISON OF PROBABILITY OF DETECTION (POD) DATA DETERMINED USING DIFFERENT STATISTICAL METHODS
A. Fahr, D. Forsyth, and M. Bullock Dec. 1993 18 p
(LTR-ST-1947; CTN-94-61063) Avail: CASI HC A03/MF A01

Different statistical methods have been suggested for determining probability of detection (POD) data for nondestructive inspection (NDI) techniques. A comparative assessment of various methods of determining POD was conducted using results of three NDI methods obtained by inspecting actual aircraft engine compressor disks which contained service induced cracks. The study found that the POD and 95 percent confidence curves as a function of crack size as well as the 90/95 percent crack length vary depending on the statistical method used and the type of data. The distribution function as well as the parameter estimation procedure used for determining POD and the confidence bound must be included when referencing information such as the 90/95 percent crack length. The POD curves and confidence bounds determined using the range interval method are very dependent on information that is not from the inspection data. The maximum likelihood estimators (MLE) method does not require such information and the POD results are more reasonable. The log-logistic function appears to model POD of hit/miss data relatively well and is easy to implement. The log-normal distribution using MLE provides more realistic POD results and is the preferred method. Although it is more complicated and slower to calculate, it can be implemented on a common spreadsheet program. Author (CISTI)

(NASA-CR-195245; NAS 1.26:195245; PRI-200) Avail: CASI HC A03/MF A01

Detection of stress cracks and other surface defects during maintenance and in-service inspection of propulsion system components, including turbine blades and combustion compartments, is presently performed visually. There is a need for a non-contact, miniaturized, and fully fieldable instrument that may be used as an automated inspection tool for inspection of aircraft engines. During this SBIR Phase 1 program, the feasibility of a ruggedized optical probe for automatic and nondestructive inspection of complex shaped objects will be established. Through a careful analysis of the measurement requirements, geometrical and optical constraints, and consideration of issues such as manufacturability, compactness, simplicity, and cost, one or more conceptual optical designs will be developed. The proposed concept will be further developed and a prototype will be fabricated during Phase 2. Derived from text

AUTOMATED FABRIC INSPECTION SYSTEM Final Report, 30 Jan. 1990 - 15 May 1993
Christine W. Jarvis 1 Oct. 1993 20 p
(Contract DLA900-87-D-0017)
(AD-A274522) Avail: CASI HC A03/MF A01

The Automatic Fabric Inspection System developed by Systronics Inc. for Clemson Apparel Research uses vision technology to acquire images of the fabric two thousand times per second. Each image-video line consisting of 2048 picture elements is analyzed by a signal processing module and a decision on defect presence and location is made. A product norm signal is first established by having the system acquire an image of an unflawed stripe of the product. The output of each picture element (pixel) is digitized to a grey scale value in the 0-255 range. Threshold levels for defects with grey scale values higher and lower than product norm can then be established and set. The system will then compare all subsequent images against the set thresholds. BASELINE FOR A NORDTEST METHOD. RELIABILITY STRESS SCREENING OF COMPONENTS. A GUIDE FOR COMPONENT USERS
Arne Boerjesson, Valter Loll, and Allan Moller Kristensen 1993 119 p
(Nordtest Proj. 1034-92)
(PB94-123775; SP-RAPP-1993:48) Avail: CASI HC A06/MF A02

A method for reliability stress screening (RSS) of components has been developed and is proposed to form a baseline for a Nordtest-method. Before issuance as a Nordtest-method, it is proposed to supplement this report regarding possible failure modes and to make some editorial changes. The development work has been done in cooperation between the Swedish National Testing and Research Institute (SP) and Elektronikcentralen (EC) and was financed by Nordtest. The method makes use of methods described in IEC standard 1163. It is complementary to Nordtest-method NT ELEC 018 which defines a method for RSS of printed wiring assemblies. The purpose of the method is to give guidance to the component user and equipment manufacturer for the specification and the performance of screening for different cases. Five cases based on the users' different aims for the screening are defined in the method. Examples of the design of a screening program are given for 4 different component generic families. These are chosen as being the component families with the highest rate of early failures as defined by a questionnaire performed during the work with the Nordtest-method NT ELEC 018. NTIS

AN UNAVAILABILITY MODEL FOR ERRORS MADE DURING SURVEILLANCE TESTING
Terry F. Bott 1993 5 p Presented at the 2nd Probabilistic Safety Assessment and Management Conference, San Diego, CA, 20-24 Mar. 1994
(Contract W-7405-eng-36)

(DE94-000816; LA-UR-93-3423; CONF-940312-13) Avail: CASI HC A01/MF A01

Periodic testing or examination is conducted routinely for some critical standby equipment or instrumentation, in an attempt to increase its availability. This is often called 'surveillance testing.' There is a finite probability that tested equipment will be left in a degraded or nonfunctioning state because of an error, and this important type of human error is often called a 'restoration error' in probabilistic safety analysis (PSA) parlance. One would expect a trade-off between the reduction in unavailability gained by a surveillance testing and the increase in unavailability incurred by surveillance testing errors. In this paper, a mathematical model of the effect of errors made during surveillance testing on equipment unavailability is described. DOE

The vibration behavior of a stiffened panel is investigated. The finite element method is employed for the computational analysis. The example structure is modeled using three different approaches. The main difference between the approaches is the way the stiffeners are modeled: as stiffener elements; or as flat shell elements. To estimate the errors, three element meshes on different levels of accuracy are used. The resulting natural frequencies and mode shapes are compared. Modal testing of the actual panel is performed. The resonant frequencies and modes of the panel are compared with numerical results. To get an idea of the effect of geometrical imperfections and residual stresses on the vibration characteristics of this kind of structure, the panel is tested both in the natural post welding state and after being straightened. DETERMINATION OF FRACTURE STRESS AND EFFECTIVE CRACK TIP RADIUS FROM TOUGHNESS (KIc) AND YIELD STRENGTH (Y) Final Report

Reinier Beeuwkes, Jr. Nov. 1993 62 p

(AD-A274014; ARL-SR-3) Avail: CASI HC A04/MF A01

This is the last of several reports in which K(sub Ic) toughness is not considered basic, but dependent on two metallurgically controllable parameters, the tensile nil-ductility fracture stress and an effective crack tip radius formed by straining at the sharp crack tip which is shown by examples not to be uniquely dependent on load as would the mathematical increase in radius of a rounded tip no matter how small, in a homogeneous material but also dependent metallurgically on micromechanical structure. How to determine the fracture stress and the radius from K(sub Ic) tests with the aid of a postulated fracture criterion characteristic of the material and a curve derived from the solution for the state of stress in the yielded region of a short elliptically shaped flat crack lying across the center of a plate under uniform tensile loading are described. A more exact solution by Colin E. Freese and Dennis M. Tracey supplants the approximate ones used previously and it is shown that dependent on tempering or test temperature, radius determinations remain unchanged to 20% larger although fracture stress determinations are 75% to 85% as large. TESTING COMPOSITE-TO-METAL TUBULAR LAP JOINTS

T. R. Guess, E. D. Reedy, Jr., and A. M. Slavin 1993 26 p Presented at the American Society for Testing Materials (ASTM) Symposium on Bolted and Bonded Joints in Composite Materials, Ft. Worth, TX, 16-17 Nov. 1993

(Contract DE-AC04-94AL-85000)

(DE94-003225; SAND-93-0018C; CONF-9311124-1) Avail: CASI HC A03/MF A01

Procedures were developed to fabricate, nondestructively evaluate, and mechanically test composite-to-metal tubular joints. The axially loaded tubular lap joint specimen consisted of two metal tubes bonded within each end of a fiberglass composite tube. Joint specimens with both tapered and untapered aluminum adherends and a plain weave E-glass/epoxy composite were tested in tension, compression, and flexure. Other specimens with tapered and untapered steel adherends and a triaxially reinforced E-glass/epoxy composite were tested in tension and compression. Test results include joint strength and failure mode data. A finite element analysis of the axially loaded joints explains the effect of adherend geometry and material properties on measured joint strength. The flexural specimen was also analyzed; calculated surface strains are in good agreement with measured values, and joint failure occurs in the region of calculated peak peel stress. DOE

GROWTH OF SMALL FATIGUE CRACKS IN INCOLOY-908

Z. Mei, C. Krenn, and J. W. Morris, Jr. Jul. 1993 8 p Presented at the International Cryogenic Engineering Conference and International Cryogenic Materials Conference, Albuquerque, NM, 12-16 Jul. 1993

(Contract DE-AC03-76SF-00098)

(DE94-003406; LBL-34018; CONF-930703-39) Avail: CASI HC A02/MF A01

Incoloy-908 was designed as a structural alloy for the conduit of cable-in-conduit superconductors. The conduit is a thin-wall tube that encloses superconducting cables. Since the conduit may be as thin as 3 to 12 mm in thickness and is subject to cyclic loads, fatigue crack growth behavior at liquid helium temperature, especially in the small crack regime, is a critical issue for magnet design. Because it is difficult to perform small fatigue crack propagation tests at 4.2 K, we have studied mechanisms of small crack propagation at room temperature and 77 K, and use the results to propose a feasible method for estimating small crack propagation at 4.2 K. THE RAILWAY TRACK RESPONSE FUNCTION
J. J. Kalker 1993 14 p
(ISSN 0922-5641)
(Rept-93-40; ETN-94-95395) Copyright Avail: CASI HC A03/MF A01

The response function of the railway track due to a traveling vertical point load running over the track with constant velocity is calculated. The rail is modeled as a Euler beam. The most important feature of the study is that the traveling of the load is fully taken into account. The complex Fourier transform is used. The response is specialized to the contact point. The expression takes the form of a convolution equation, with the vertical displacement left, and the intensity of the vertical point load and an influence function right. An integral representation of the influence function is given. The calculation should be extended to tangential loads. ESA

HYPERMEDIA SUPPORT FOR ENGINEERING DESIGN SYSTEMS: APPLICATION TO FATIGUE ANALYSIS
Juha Saeaeski, Sisko Sipilae, and Gary Marquis Dec. 1992 26 p
Sponsored by Technical Research Centre of Finland, Espoo
(ISSN 1235-0605)
(VTT-TIED-1432; ISBN-951-38-4326-2; ETN-94-95259) Copyright Avail: CASI HC A03/MF A01

The possibilities of using hypermedia for supporting engineering design systems are discussed. The application selected to test the hypermedia ideas was fatigue analysis. In addition, the possibility of combining hypermedia and expert system ideas into a fatigue expert system is reported. Hypermedia's underlying notion of linking nodes of information and its capability to handle these information entities stored appear to be well suited for engineering system support systems, especially in those engineering design systems where there exists a great demand for representing graphical information in a convenient way. This can be realized using hypermedia tools that are based on hypermedia techniques. The resulting fatigue handbook covers only part of the hypermedia's possibilities. The development of a prototype application indicates the efficiency of a hypermedia tool to create an electronic manual. ESA

Guidelines for obtaining and using Environmentally Assisted Cracking (EAC) test data for stainless steels, which are used in a wide range of industrial applications, are presented. Both fracture mechanics and non fracture mechanics tests and test results for Stress Corrosion Cracking (SCC) and Corrosion Fatigue (CF) are considered, but the emphasis is on using fracture mechanics as part of an overall strategy (a fracture control plan) to prevent or control EAC in service. Various threshold values for cracking to occur are reviewed based on loading, electrochemistry, solution chemistry, and temperature. ESA

Part of the pressure tubes surveillance program of CANDU type reactors is to determine the fracture toughness using a special fracture specimen and test procedure. Atomic Energy of Canada Limited decided to hold a Round Robin Test International and 9 laboratories participated worldwide in which several pressure tube materials were selected: Zircaloy-2, Zr-2.5%Nb cold worked and Zr-2.5%Nb heat treated. The small specimens used held back the thickness and curvature of the tube. J-R curves at room temperature were obtained and the crack extension values were determined by electrical potential drop techniques. These values were compared with results generated from other laboratories and a bid scatter was founded. It could be due to slight variations in the test method or inhomogeneity of the materials and a statistical study must be done to see if there is any pattern. The next step for the Round Robin Test would be to make some modifications in the test method in order to reduce the scatter. DOE

Fire safety is discussed in general terms, together with some other factors affecting the fire resistance of a structure and structural elements. Neither the development of fire nor temperature dependent material properties are discussed. Many research reports presented dealing with the behavior of structures and structural elements during fire as well as the behavior of connections in a fire contain valuable advice on how to design structures and element connections so that in the case of fire they are better protected, both with regard to the users of the building and the fire brigade. Studies concerning real fires and experience obtained from large scale fire tests are presented. A report in which the real need and possibilities for repairing structures or structural elements after a fire are discussed is presented. The repair methods are also presented. ESA

RESPONSE SURFACE DESIGN COMPARISONS Final Report, May 1992 - 1993
Ronald B. Crosier Oct. 1993 19 p
(DA Proj. 1O1-61102-A-71-A)
(AD-A274690; ERDEC-TR-126) Avail: CASI HC A03/MF A01

Response surface designs are often compared by optimal design theory criteria, such as the D- and G-efficiencies. For designs over spherical regions such criteria are calculated after scaling the designs to have the same diameter. But in practice designs are applied by scaling the coded factor ranges (not the diameter) to the ranges of the experimental factors. The result of this discrepancy between theory and practice is that the mathematical efficiencies may apply to regions of varying sizes. Further, there are practical objectives, such as minimizing the number of runs or testing for lack of fit, that are ignored by optimal design theory. Two examples were given to show the limitations of optimal design theory comparisons. For many symmetric second-order designs, a table giving the following items was provided: number of noncentral design points, number of levels, number of orthogonal blocks, diameter/range ratio, and G-efficiency. EARLY STAGES IN THE DEVELOPMENT OF STRESS CORROSION CRACKS
R. H. Jones and E. P. Simonen 1993 29 p Presented at the 4th International Conference on Fundamentals of Fracture, Urabandai, Japan, 30 May - 4 Jun. 1993
(Contract DE-AC06-76RL-01830)
(DE94-003867; PNL-SA-21753; CONF-9305312-1) Avail: CASI HC A03/MF A01

Processes in growth of short cracks and stage 1 of long stress corrosion cracks were identified and evaluated. There is evidence that electrochemical effects can cause short stress corrosion cracks to grow at rates faster or slower than long cracks. Short cracks can grow at faster rates than long cracks for a salt film dissolution growth mechanism or from reduced oxygen inhibition of hydrolytic acidification. An increasing crack growth rate with increasing crack length could result from a process of increasing crack tip concentration of a critical anion, such as Cl(-), with increasing crack length in a system where the crack velocity is dependent on the Cl(-) or some other anion concentration. An increasing potential drop between crack tip and mouth would result in an increased anion concentration at the crack tip and hence an increasing crack velocity. Stage 1 behavior of long cracks is another early development stage in the life of a stress corrosion crack which is poorly understood. This stage can be described by da/dt = AK(sup m) where da/dt is crack velocity, A is a constant, K is stress intensity and m ranges from 2 to 24 for a variety of materials and environments. Only the salt film dissolution model was found to quantitatively describe this stage; however, the model was only tested on one material and its general applicability is unknown. DOE

USER'S GUIDE FOR THE FREQUENCY DOMAIN ALGORITHMS IN THE LIFE2 FATIGUE ANALYSIS CODE
H. J. Sutherland and R. L. Linker (New Mexico Univ., Albuquerque.) Oct. 1993 53 p
(Contract DE-AC04-94AL-85000)
(DE94-004678; SAND-93-1900) Avail: CASI HC A04/MF A01

The LIFE2 computer code is a fatigue/fracture analysis code that is specialized to the analysis of wind turbine components. The numerical formulation of the code uses a series of cycle count matrices to describe the cyclic stress states imposed upon the turbine. However, many structural analysis techniques yield frequency-domain stress spectra and a large body of experimental loads (stress) data is reported in the frequency domain. To permit the analysis of this class of data, a Fourier analysis is used to transform a frequency-domain spectrum to an equivalent time series suitable for rainflow counting by other modules in the code. This paper describes the algorithms incorporated into the code and their numerical implementation. Example problems are used to illustrate typical inputs and outputs. DOE

THE FREE VIBRATION OF PLATES, SHALLOW SHELLS AND SOLIDS Ph.D. Thesis
Philippe Georges Young Jul. 1993 191 p
(ISBN-0-315-83931-7; CTN-94-61045) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The Ritz approach is used to study the free structural vibration problem of a wide class of plates, shallow shells, and solids. The boundaries and/or internal supports of the systems are considered and described by polynomials in Cartesian coordinates. The geometric boundary conditions at these boundaries or supports are enforced by including in a simple polynomial trial series the polynomial equation describing the position of the support raised to the appropriate power. For plates and shallow shells, in some instances, the displacement field is discretized into several domains or elements, and continuity conditions along the connecting boundaries are enforced using a penalty method approach. Complicating effects such as point masses, stepped geometry, cutouts, and internal point supports are also considered. The natural frequencies and mode shapes of isotropic rectangular plates are obtained, then isotropic and orthotropic plates of more general form are considered. The approach is extended to shallow shells of differing shapes and curvatures, as well as complicating effects. The approach is finally applied to studying free vibration of a class of solids including a sphere, cylinders, a cone, and a prismatic solid of more general cross-section. Author (CISTI)

DYNAMICS OF A FLEXIBLE EXTENDIBLE BEAM Ph.D. Thesis

Marinos Costa Stylianou 1993 192 p
(ISBN-0-315-84278-4; CTN-94-61018) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Axially moving materials arise in problems associated with spacecraft antennas, pipes conveying fluid, and telescopic robotic manipulators. Hamilton's principle is used to derive the governing differential equation of motion and system invariant properties of a flexible extendible beam (FEB) protruding from a rigid wall with prescribed extrusion profile. Numerical solutions are obtained using finite element analysis in which the number of elements is fixed while the sizes of the elements change with time. To this end, a variable domain beam finite element whose size is a prescribed function of time is formulated. The accuracy of this variable domain beam element is demonstrated through the time integration of equations of motion using various extrusion profiles. Additional verification is performed by the evaluation of the system's invariant quantities, comparison with special analytical solution, and the dynamic stability analysis of pipes conveying fluid. The effects of wall flexibility, tip mass, and high frequency axial motion perturbations to the transverse response of the FEB are also examined. The versatility and power of the finite element formulation is demonstrated in a simulation of an extruding FEB which carries a tip mass and protrudes from a flexible envelope beam which imparts three dimensional rigid-body rotations to the system. IDENTIFICATION AND H(INFINITY)/(MU)-SYNTHESIS CONTROL OF THE SANDIA TRUSS
James J. Allen and James P. Lauffer 1993 15 p Presented at the 4th International Conference on Adaptive Structure, Cologne, Germany, 2-3 Nov. 1993
(Contract DE-AC04-94AL-85000)
(DE94-002735; SAND-93-1119C; CONF-9311119-1) Avail: CASI HC A03/MF A01

This paper presents an overview of an analytical and experimental system identification and control design study performed on a controlled structure test bed, the Sandia Truss. The purpose of this project was to assess the capability of several identification and control methods for vibration suppression of large structures. The Sandia Truss, like most structures, represents a challenge to the existing identification and control methods due to high modal density, closely coupled dynamics, external unmeasured inputs, and frequency regimes with poor signal-to-noise characteristics. Because large space structures will require a coordinated control involving multiple disturbances and control objectives, such as line of sight or system quiescence at a specified location, this study focused on multiple-input/multiple-output identification and control. For the study reported in this paper, control design models were developed from experimentally obtained data using the Eigensystem Realization Algorithm with Data Correlation (ERADC); and, the control design was performed using the H(infinity)/(mu)-synthesis technique. GEOMETRY CHANGES IN THE ELASTIC-PLASTIC ANALYSIS OF STEEL SPATIAL SKELETAL STRUCTURES Ph.D. Thesis
Hosain Mohamed H. Bondok 1993 162 p
(IFTR-37/1993) Avail: CASI HC A08/MF A02

The principal objective is to furnish a tool for aunified formulation and numerical analysis of all the history-independent classes of response of elastic perfectly plastic space skeletal structures. We aim at determination of load domains corresponding to elastic, shakedown and collapse behavior for structures in initial and deformed configurations. Numerical program SDLAS for post-yield and inadaptation (non-shakedown) analysis of elastic-plastic space skeletal structures was prepared. It accounts for biaxial bending, torsion and axial forces contributing to yielding of beam elements. The program permits to determine a safe domain for either proportional or variable repeated loads. The proposed method accounts for nonlinear geometrical effects. In the post-yield analysis the conditions for plastic now are considered at subsequent deformed configurations. For the inadaptation analysis the similar procedure is applied. Automatic generation of all possible plastic deformation modes allows to select the most dangerous mechanisms and to determine a critical plastic deformation path. Finally, the post-yield or inadaptation curve is obtained showing the dependence of load (load domain) multiplier on the plastic deformation. These problems are formulated as a sequence of linear programming tasks and are solved by a step by step procedure. The proposed method allows to determine the limit multiplier and the shakedown (adaptation) multiplier accounting for geometric effects. Author

EVALUATION OF CRACK ARREST FRACTURE TOUGHNESS OF PARENT PLATE, WELD METAL AND HEAT AFFECTED ZONE OF BIS 812 EMA SHIP PLATE STEEL
I. A. Burch Oct. 1993 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A274871; MRL-TR-93-9; DODA-AR-008-267) Avail: CASI HC A03

The steel chosen for the pressure hull of the Collins class submarine has undergone evaluation to compare the crack arrest fracture toughness, K(Ia), of the parent plate with that of weld metal and heat affected zone. The tests were conducted over a range of subzero temperatures on specimens slightly outside the ASTM standard test method specimen configuration. Shallow face grooved specimens were used to vary the propagating crack velocity from that of non face grooved specimens and determine if K(Ia), is sensitive to changes in crack velocity. The weld metal, heat affected zone (HAZ), and parent plate were assessed to determine if the welding process had a deleterious effect on the crack arrest properties of this particular steel. Tests on each of these regions revealed that, for the combination of parent plate, welding procedure and consumables, no adverse effect on crack arrest properties was encountered. Crack arrest fracture toughness of the weld metal and HAZ was superior to that of the parent plate at comparable temperatures. DTIC

REFINED TRIANGULAR PLATE AND SHELL ELEMENTS Ph.D. Thesis
F. vanKeulen 26 Jan. 1993 128 p
(PB94-126356) Avail: CASI HC A07/MF A02

In this work several refinements of small strain triangular plate and shallow shell elements are discussed. These element types are closely connected in the present work, because the shell elements are formulated on the basis of the plate bending elements. In Chapter 3, a family of plate bending elements is discussed, based upon the Kirchhoff-Love and the Mindlin-Reissner plate models. Refinements of the facet element, which is a combination of the constant strain and the constant bending moment triangle, are presented in Chapter 4. In Chapter 5 an alternative finite rotation formulation is presented, which is applicable to arbitrary rotational increments. Based upon the plate bending elements with linear variations for the bending moments, more complex elements are established in Chapter 6. Throughout the work several numerical examples are given. These examples show characteristic features of the refined elements and yield a comparison with former formulations and some elements known from literature. NTIS

COMPUTATION OF STRESS INTENSITY FACTORS BY THE MODE ENRICHMENT TECHNIQUE WITH APPLICATIONS TO GEOMETRICALLY NONLINEAR PROBLEMS

H. A. J. Knops Feb. 1993 67 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-126513; LR-712) Avail: Issuing Activity (National Technical Information Service (NTIS))

Standard computational methods for the determination of crack tip stress intensity factors need adaptation if they are to be used for crack problems that are governed by geometrically nonlinear effects. This is also true for the so-called mode enrichment technique, a technique whereby (generalized) local crack tip solutions are used as additional trial functions in a finite element modeling scheme. The paper discusses some of the fine points of this adaptation. One of the advantages of the mode enrichment method is that it produces the complete set of intensity factors that belong to the various modes of cracking. From the practical evaluation of this approach it appears that the method is versatile and accurate, attributes that make it an attractive alternative amongst rival methods. NTIS

FORMULAE FOR THE BUCKLING OF SIMPLY-SUPPORTED CORRUGATED PANELS OF ORTHOTROPIC MATERIAL UNDER SHEAR LOAD

P. G. VanBladel Mar. 1993 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-126547; LR-716) Avail: Issuing Activity (National Technical Information Service (NTIS))

This report presents formulae for the shear buckling of corrugated panels made of orthotropic materials. The formulae developed are to be incorporated in COPANO, a computer program for corrugated panel analysis and optimization. The corrugated panels considered in COPANO can be made of composite material, with orthotropic properties. Both the buckling analysis and the optimization are then much more involved than if isotropic material was used. The buckling analysis then has to take into account more stiffness parameters. Also, the optimization necessitates simple buckling calculations without recourse to numerical iteration procedures, to limit the time consumed in the analysis. These characteristics determine to a large extent the type of buckling formulae developed here. NTIS

DESIGN AND TEST OF POSTBUCKLED STIFFENED CURVED PLATES: A LITERATURE SURVEY

J. L. Verolme Feb. 1993 35 p
(PB94-126521; LR-711) Avail: CASI HC A03/MF A01

A designer's tool for compressive buckling of aircraft fuselage panels, currently being developed at the Structures and Materials Laboratory of the Faculty of Aerospace Engineering of Delft University of Technology, must be validated with experimental results. The tested materials will be either isotropic (metal), orthotropic (GLARE, a fiber-metal laminate), or anisotropic (fibre reinforced plastics). For the formulation of a test matrix, a literature survey concentrating on tests of flat and curved, stiffened and unstiffened plates is performed. At the same time, simple semi-empirical formulas are collected to construct a design procedure based on these formulas. The design procedure can be checked and validated with the results of the literature survey. NTIS

(Contract N00014-91-C-0067)
(AD-A274504) Avail: CASI HC A03/MF A01

This program aims at improving current methods of lifetime assessment by building in the characteristics of the micromechanisms known to be responsible for damage and failure. The broad approach entails the integration and, where necessary, augmentation of the microscale research results currently available in the literature into a macroscale model with predictive capability. In more detail, the program will develop a set of hierarchically structured models at different length scales, from atomic to macroscopic, at each level taking as parametric input the results of the model at the next smaller scale. In this way the known microscopic properties can be transported by systematic procedures to the unknown macroscale region. It may not be possible to eliminate empiricism completely, because some of the quantities involved cannot yet be estimated to the required degree of precision. In this case the aim will be at least to eliminate functional empiricism. Restriction of empiricism to the choice of parameters to be input to known functional forms permits some confidence in extrapolation procedures and has the advantage that the models can readily be updated as better estimates of the parameters become available.

SAG COMPENSATED VIBRATION ISOLATION MOUNT Patent Application
Stuart Dickinson, inventor (to Navy) 2 Aug. 1993 15 p
(AD-D016040; US-Patent-Appl-SN-100798) Avail: CASI HC A03/MF A01

A sag-compensated vibration isolation mount includes a cylindrical rubber body element and a circular band extending around the body element. The band is formed from a shape-memory alloy metal which has a predetermined transition temperature. The band is operative for restricting, outward bulging and sagging of the body element when the body element is subjected to an axial load at a temperature above the transition temperature. The band has a first length at a temperature above the transition temperature and it is stretchable to a second length at a temperature below the transition temperature. At temperatures below the transition temperature, the body element normally stretches the band to its second length. However, when the band is heated above its transition temperature, the band rapidly decreases in length to its first length to forcibly compress the body element and restrict outward bulging of the body element.

Methods for practical engineering fracture and fatigue analysis of flawed thick walled components were developed. Aims are at improving the applicability of the three dimensional finite element method in calculating fracture mechanical parameters for surface flaws. A method for approximating weight functions for flawed structures is developed. The ACR (automatic finite element model generation for part through cracks) program was developed for modeling a surface crack in a structure with a three dimensional finite element model. The modeling of the crack area was tested by analyzing a large matrix of surface crack sizes in a plate of finite thickness. A local mesh refinement procedure was developed for systematic improvement of the accuracy of the fracture parameters. The weight function method developed was implemented in the VTTSIF (Technical Research Center of Finland Stress Intensity Factor) program. For individual titles, see N94-27187 through N94-27190.

A program system for fracture assessment of nuclear power plant structures was developed. The system consists of a program for engineering analysis and an automated finite element program system for accurate analysis with solid three dimensional models. The VTTSIF (Technical Research Center of Finland Stress Intensity Factor) program for engineering fracture assessment applies either the weight function method or superposition method in calculating the stress intensity factor. The fatigue crack growth analysis is based on the Paris equation. The generation of a three dimensional finite element model of a cracked structure is automated by the ACR (automatic finite element model generation for part through cracks) program. The finite element analyses are created with commercial programs. The virtual crack extension method is used for fracture parameter evaluation by the VTTVIRT postprocessor program (program for J-integral evaluation using virtual crack extension method). The test cases demonstrated that the accuracy of the system is satisfactory.

METHOD FOR CALCULATING STRESS INTENSITY FACTORS FOR SURFACE CRACKS (APPENDIX 2/1)
Timo P. J. Mikkola *In its* Numerical Analysis Methods of Surface Cracks Oct. 1992 18 p Repr. from Engineering Fracture Mechanics, v. 42, no. 5, 1992 p 713-730 Sponsored by Teollisuuden Voima Oy, Finland, and Imatran Voima Oy, Helsinki, Finland (For primary document see N94-27186 07-39)
Copyright Avail: CASI HC A03/MF A02

An approximate weight function method for calculating stress intensity factors for semi elliptical surface cracks under arbitrary loads is presented. The crack face displacement field required for the calculation is approximated by using one or more known stress intensity factor solutions. The method is applied to surface cracks in a wide plate using published analytical solutions for tension and bending loads as reference solutions. The results were compared with other published results. Different displacement approximation functions were tested. The two parameter displacement approximation gave good accuracy when the tension solution was used as the reference case. The addition of the third parameter improved the results for several load cases. The accuracy of the method is best at the deepest position of the crack. The stress intensity factor for the analyzed load case is interpolated along the crack front with only two interpolation functions. More than two interpolation functions can be used if the weight function equation is applied several times using more than one linearly independent reference solution. This was tested with the two currently available reference solutions, but the tests were not successful.

QUALITY ASSURANCE FOR FRACTURE MECHANICAL FINITE ELEMENT ANALYSES (APPENDIX 3/1)
Timo P. J. Mikkola and H. Niemi *In its* Numerical Analysis Methods of Surface Cracks Oct. 1992 9 p Repr. from Computers and Structures, v. 40, no. 2, 1991 p 271-279 Sponsored by Teollisuuden Voima Oy, Finland, and Imatran Voima Oy, Helsinki, Finland (For primary document see N94-27186 07-39)
Copyright Avail: CASI HC A02/MF A02

A program system for automated fracture mechanical analyses with three dimensional finite element models was developed. The main application was safety analyses of pressurized components of nuclear power stations such as pipes and pipe bends containing surface cracks. The system is extended to surface cracks in reactor pressure vessel nozzle area. A large matrix of varying surface crack sizes in a plate under tension is analyzed and the automatically generated mesh obtained good accuracy. The tests do not guarantee the same accuracy for general loading conditions and geometries. Methods for the accuracy assessment of the results and for directing the mesh refinement are developed. Results of a test series with plane models are promising. In the mesh refinement element subdivision was used. The same accuracy assessment approach is applied to three dimensional models.

APPLICATIONS OF THE WEIGHT FUNCTION METHOD (APPENDIX 4/1)
Timo P. J. Mikkola *In its* Numerical Analysis Methods of Surface Cracks Oct. 1992 37 p Submitted for publication Sponsored by Teollisuuden Voima Oy, Finland, and Imatran Voima Oy, Helsinki, Finland (For primary document see N94-27186 07-39)
Copyright Avail: CASI HC A03/MF A02

New solutions for the stress intensity factor and the crack opening displacement at the crack center for the semi elliptical surface crack in a wide plate under remote tension and bending loads were developed. The solutions were based on results of finite element analyses made by an automated program system. The accuracy of the results was studied. The solutions were used for developing weight functions for the structure. The accuracy of these weight functions were tested. The present automated finite element analysis of surface cracks can be applied to practically any structural geometry. A weight function for a surface crack in a weld connecting a nozzle to a pressure vessel was developed. The accuracy of the present weight function method is sufficient for practical applications. MODIFICATION OF A MODEL FOR FATIGUE LIFE PREDICTIONS BASED ON LEVEL-CROSSING [MODIFIERAD MODELL FOER LIVSLAENGDSBERAEKNING UTGAENDE FRAN NIVAOEVERSKRIDANDE]
T. Svensson 1993 43 p In SWAHILI
(PB94-123395; SP-RAPP-1993-46) Avail: Issuing Activity (National Technical Information Service (NTIS))

In this report, a method of fatigue life prediction is presented. The method is based on level-crossing and is a modification of a model by Holm and de Mare (HdM). The HdM-model is modified by taking crack closure into account. Variable amplitude and constant amplitude tests are performed on both stainless steel and structural steel. The test results are used to compare the HdM-method, the modified HdM-method, and the RFC-method for load spectra with various irregularities and shapes. Life predictions made with the modified HdM-method are at least as good as the life predictions made with the traditional RFC-method. The original HdM-method often predicts the fatigue life in a conservative way. NTIS

(ISBN-0-315-84564-3; CTN-94-61077) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The chaotic behavior of a parametrically forced Holmes-Duffing oscillator is studied using methods of nonlinear dynamics. By employing the Poincare map, it is shown that a qualitative understanding of chaotic oscillations can be obtained by studying the discrete dynamics of two-dimensional diffeomorphisms. Both numerical and perturbation methods are used to justify the application of several known theoretical results which describe the onset of chaos in one-parameter families of maps, in particular the Poincare map of the Holmes-Duffing oscillator. The geometry of equipment and x-ray diffraction criteria were examined to optimize for precision in measurements of residual stress/strain in composite materials while maintaining tolerable measurement times. The resulting diffractometer and a cohabiting texture acquisition system were applied in measuring residual stress states in three composite systems. In SiC-reinforced Al, non-isotropic and triaxial tensile stresses were measured, with the stress magnitude increasing with decreasing reinforcement size. In TiB2-reinforced NiAl, slightly non-isotropic, triaxial, and tensile stresses were found in the matrix. The stress magnitudes were lower than expected, possibly due to the presence of alpha alumina. In a specimen of ridged AISi 430 ferritic stainless steel, stresses were measured in two texture components. A strong compressive stress was found in the transverse direction in the component supporting the buckling model for ridge formation. The development of techniques for precise low angle measurements allowed application to triaxial stress determination as a function of temperature in thin film metallization structures. A modified interfacial diffusion controlled relaxation model was proposed to explain the greater relaxation observed in Al(Cu) films compared to pure Al films. Author (CISTI)

The response of beams and rectangular plates to impact loads is examined. When the deformations are in the elastic region, normal mode analysis is used to find the response. The Rayleigh-Ritz method is employed to obtain the natural frequency and mode shape coefficients. Different types of displacement shape functions are used in the analysis, functions such as beam characteristic functions and beam characteristic orthogonal polynomials. An approximate plate function is determined by reduction of the plate partial differential equation and solving the resulting ordinary differential equation as in the Kantarovich method, then using the Rayleigh-Ritz method. The same reduction procedure is also used along with successive iteration until convergence to obtain the natural frequencies and mode shape functions directly. Structural response to impact loads is also examined using rigid plastic analysis. A cantilever beam with impulsive load applied at the free end, and with finite blade radius and varying centrifugal forces, is considered. Experimental simulation of impact loading used a mass falling from a known height onto the structure under investigation. The elastic response of a plate with two adjacent edges clamped and the other two free was studied. An equivalent mathematical model was formulated by using flexible edge supports. Author (CISTI)

A space truss is a three dimensional structural system assembled of linear elements arranged so that forces are transferred in a three dimensional manner. Space trusses are used where large unobstructed spaces are required, such as aircraft hangars. Space trusses have the advantages of light weight, ease of assembly, ability to create multipurpose architectural spaces, and aesthetic appeal. Space trusses are designed using linear elastic theory, and their load carrying capacity is considered to be limited by the failure of a few critical members. Due to high redundancy and practical constraints, only a portion of the truss member strength is used. Modification of space truss behavior is studied by introducing nonlinearity in the chord members prior to attaining their maximum load. The amount of nonlinearity required to increase the load capacity of the truss by an economically justifiable amount is determined, and the feasibility of the proposed system was confirmed by tests on the elements and an assembled truss. Alternatively, transfer of load to understressed elements can be achieved by selective removal of internal bracing members. A means to determine the optimum selection of diagonals to be removed has been established. The above techniques were applied to four similar space trusses with different support conditions and member size distribution.

VIBRATIONS IN ENGINEERING STRUCTURES: A REVIEW OF MODEL AND FULL-SCALE TEST OF A CABLE-STAYED BRIDGE AND A TRAFFIC SIGN GANTRY

A. J. Persoon 21 Aug. 1992 24 p Presented at the 2nd International Colloquium on Bluff Body Aerodynamics and Applications, Melbourne, Australia, 7-10 Dec. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NLR-TP-92321-U; ETN-94-95451) Avail: CASI HC A03

As an example of investigations performed on different slender structures submitted to dynamic wind loading, research on a cable stayed bridge and a traffic sign gantry is discussed. The bridge was primarily investigated in the wind tunnel on 'vortex induced' vibrations. Afterwards, full scale measurements were carried out. The sign gantry appeared to be sensitive to 'galloping' oscillations at the site. This was confirmed by wind tunnel tests.

STRUCTURAL DESIGN FEASIBILITY STUDY OF SPACE STATION LONG SPACER TRUSS

Sasan C. Armand, Gregory P. Funk, and Caroline A. Dohogne Feb. 1994 28 p Original contains color illustrations
(RTOP 474-46-10)
(NASA-TM-106346; E-8117; NAS 1.15:106346) Avail: CASI HC A03/MF A01; 2 functional color pages

The structural design and configuration feasibility of the long spacer truss assembly that will be used as part of the Space Station Freedom is the focus of this study. The structural analysis discussed herein is derived from the transient loading events presented in the Space Transportation System Interface Control Document (STS ICD). The transient loading events are liftoff, landing, and emergency landing loads. Quasi-static loading events were neglected in this study since the magnitude of the quasi-static acceleration factors is lower than that of the transient acceleration factors. Structural analysis of the proposed configuration of the long spacer truss with four longerons indicated that negative safety margins are possible. As a result, configuration changes were proposed. The primary configuration change suggested was to increase the number of truss longerons to six. The six-longeron truss appears to be a more promising structure than the four-longeron truss because it offers a positive margin of safety and more volume in its second bay (BAY2). This additional volume can be used for resupply of some of the orbital replacement units (such as a battery box). Note that the design effort on the long spacer truss has not fully begun and that calculations and reports of the negative safety margins are, to date, based on concept only.

Damped free vibrations of composite laminates are subjected to macromechanical analysis. Two models are developed: a viscoelastic damping model and a specific damping capacity model. The important symmetry property of the damping matrix is retained in both models. A modified modal strain energy method is proposed for evaluating modal damping in the viscoelastic model using a real (instead of a complex) eigenvalue problem solution. Numerical studies of multidegree of freedom systems are conducted to illustrate the improved accuracy of the method compared to the modal strain energy method. The experimental data reported in the literature for damped free vibrations in both polymer matrix and metal matrix composites were used in finite element analysis to test and compare the damping models. The natural frequencies and modal damping were obtained using both the viscoelastic and specific models. Results from both models are in satisfactory agreement with experimental data. Both models were found to be reasonably accurate for systems with low damping. Parametric studies were conducted to examine the effects on damping of the side to thickness ratio, the principal moduli ratio, the total number of layers, the ply angle, and the boundary conditions.

The objective of this Phase I research was to establish the required software and hardware strategies to achieve large scale parallelism in solving PCM problems. To meet this objective, several investigations were conducted. First, we identified the multiple levels of parallelism in PCM and the computational strategies to exploit these parallelisms. Next, several software and hardware efficiency investigations were conducted. These involved the use of three different parallel programming paradigms and solution of two example problems on both a shared-memory multiprocessor and a distributed-memory network of workstations.

USE OF PHOTOSTRESS AND STRAIN GAGES TO ANALYZE BEHAVIOR OF WELDMENTS Final Report

S. C. Gambrell, Jr. 1993 246 p Prepared for Alabama Univ., Huntsville Original contains color illustrations
(Grant NAG8-293)
(NASA-CR-195269; NAS 1.26:195269; BER-591-97) Avail: CASI HC A11/MF A03; 16 functional color pages

Tensile and pure bending tests were conducted on specimens having welded joints made from 2219-T87 aluminum alloy and 2319 filler. Data were collected using photoelastic coatings and strain gages. Stress-strain relationships and contraction ratios were determined at several points in a grid covering the weld material and heat affected zone. Material behavior was nonlinear and nonuniform at all points in the grid and contraction ratios did not conform to those predicted by Chakrabarty's plasticity theory. Yielding in joints made using four new welding procedures was examined. None of the new procedures produced more uniform yielding in the joint.

The Thermal/Structural Tailoring of Engine Blades (T/STAEBL) system is a computer code that is able to perform numerical optimizations of cooled jet engine turbine blades and vanes. These optimizations seek an airfoil design of minimum operating cost that satisfies realistic design constraints. This report documents the organization of the T/STAEBL computer program, its design and analysis procedure, its optimization procedure, and provides an overview of the input required to run the program, as well as the computer resources required for its effective use. Additionally, usage of the program is demonstrated through a validation test case. Author

SUPER FINITE ELEMENTS FOR NONLINEAR STATIC AND DYNAMIC ANALYSIS OF STIFFENED PLATE STRUCTURES Ph.D. Thesis

Tamunoiyala Stanley Koko Oct. 1990 225 p
(ISBN-0-315-63903-2; CTN-94-60998) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

New plate and stiffener beam finite elements are developed for the nonlinear static and dynamic analysis of stiffened plate structures. The elements are specially designed to contain all the basic modes of deformation response which occur in stiffened plates. Only one plate element per bay or one beam element per span is needed to achieve engineering design level accuracy at minimum cost. The Von Karman large deflection theory is used to model the nonlinear geometric behavior. Material nonlinearities are modeled by Von Mises yield criterion and associated flow rule using a bilinear stress strain law. The finite element equations are derived using the virtual work principle and the matrix quantities are evaluated by Gauss quadrature. Temporal integration is carried out using the Newmark-beta method with Newton-Raphson iteration. A computer code was written to implement the theory. This was applied to the static, vibration, and transient analysis of unstiffened plates, beams, and plates stiffened in one or two orthogonal directions. Good approximations were obtained for both linear and nonlinear problems. The displacement and stress responses obtained compare well with experimental, analytical, or other numerical results. SERIES SOLUTION FOR A CYLINDRICAL COMPOSITE SHELL SUBJECT TO AXISYMMETRIC LOADINGS Ph.D. Thesis

D. W. Lindstrom Jul. 1990 204 p
(ISBN-0-315-60559-6; CTN-94-61000) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Elasticity equations were solved to an arbitrary degree of precision for a thick-walled orthotropic cylinder subject to axisymmetric loading. The theory is directly applicable to a layered composite material where each layer is orthotropic in character. The solution proceeds by representing the deformations of the cylinder wall as a power series in a nondimensional radial parameter. By introducing a generalized stress resultant and a generalized stiffness for the material, a series of coupled second order differential equations in the coefficients of the deformation series results. These were solved using a generalized eigenvalue technique for an infinitely long cylinder, a simply held cylinder, and a rigidly clamped cylinder. The solution was shown to reduce to standard shell solutions for thin cylinders. A thick-walled filament wound test specimen is also described that when fabricated and pressurized would experimentally verify the refined theory developed. Author (CISTI)

SILICON DEVICE PERFORMANCE MEASUREMENTS TO SUPPORT TEMPERATURE RANGE ENHANCEMENT Final Report, 7 May 1990 - 31 Jan. 1994

James Bromstead, Bennett Weir, R. Mark Nelms, R. Wayne Johnson, and Ray Askew 28 Mar. 1994 84 p
(Contract NCC3-175)
(NASA-CR-195265; NAS 1.26:195265) Avail: CASI HC A05/MF A01

Silicon based power devices can be used at 200 C. The device measurements made during this program show a predictable shift in device parameters with increasing temperature. No catastrophic or abrupt changes occurred in the parameters over the temperature range. As expected, the most dramatic change was the increase in leakage currents with increasing temperature. At 200 C the leakage current was in the milliAmp range but was still several orders of magnitude lower than the on-state current capabilities of the devices under test. This increase must be considered in the design of circuits using power transistors at elevated temperature. Three circuit topologies have been prototyped using MOSFET's and IGBT's. The circuits were designed using zero current or zero voltage switching techniques to eliminate or minimize hard switching of the power transistors. These circuits have functioned properly over the temperature range. One thousand hour life data have been collected for two power supplies with no failures and no significant change in operating efficiency. While additional reliability testing should be conducted, the feasibility of designing soft switched circuits for operation at 200 C has been successfully demonstrated. Author

RELIABILITY-BASED STRUCTURAL OPTIMIZATION: A PROPOSED ANALYTICAL-EXPERIMENTAL STUDY

W. Jefferson Stroud and Efstratios Nikolaidis (Virginia Polytechnic Inst. and State Univ., Blacksburg.) Dec. 1993 24 p
(RTOP 505-63-53-01)
(NASA-TM-109055; NAS 1.15:109055) Avail: CASI HC A03/MF A01

An analytical and experimental study for assessing the potential of reliability-based structural optimization is proposed and described. In the study, competing designs obtained by deterministic and reliability-based optimization are compared. The experimental portion of the study is practical because the structure selected is a modular, actively and passively controlled truss that consists of many identical members, and because the competing designs are compared in terms of their dynamic performance and are not destroyed if failure occurs. The analytical portion of this study is illustrated on a 10-bar truss example. In the illustrative example, it is shown that reliability-based optimization can yield a design that is superior to an alternative design obtained by deterministic optimization. These analytical results provide motivation for the proposed study, which is underway. Author

The NASA-UVA Light Aerospace Alloy and Structures Technology (LA2ST) Program was initiated in 1986, and continues a high level of activity, with projects being conducted by graduate students and faculty advisors in the Departments of Materials Science and Engineering, and Mechanical and Aerospace Engineering at the University of Virginia. This work is funded by the NASA-Langley Research Center under Grant NAG-1-745. Here, we report on progress achieved between July 1 and December 31, 1993. The objective of the LA2ST Program is to conduct interdisciplinary graduate student research on the performance of next generation, light weight aerospace alloys, composites and thermal gradient structures in collaboration with NASA-Langley researchers. Specific technical objectives are presented for each research project. We generally aim to produce relevant data and basic understanding of material mechanical response, environmental/corrosion behavior, and microstructure; new monolithic and composite alloys; advanced processing methods; new solid and fluid mechanics analyses; measurement and modeling advances; and critically, a pool of educated graduate students for aerospace technologies. AN OPTIMIZATION PROGRAM BASED ON THE METHOD OF FEASIBLE DIRECTIONS: THEORY AND USERS GUIDE

Ashok D. Belegundu (Pennsylvania State Univ., University Park.), Laszlo Berke, and Surya N. Patnaik (Ohio Aerospace Inst., Brook Park.) Washington Jan. 1994 15 p
(RTOP 505-63-5B)
(NASA-TM-4552; E-8124; NAS 1.15:4552) Avail: CASI HC A03/MF A01

The theory and user instructions for an optimization code based on the method of feasible directions are presented. The code was written for wide distribution and ease of attachment to other simulation software. Although the theory of the method of feasible direction was developed in the 1960's, many considerations are involved in its actual implementation as a computer code. Included in the code are a number of features to improve robustness in optimization. The search direction is obtained by solving a quadratic program using an interior method based on Karmarkar's algorithm. The theory is discussed focusing on the important and often overlooked role played by the various parameters guiding the iterations within the program. Also discussed is a robust approach for handling infeasible starting points. The code was validated by solving a variety of structural optimization test problems that have known solutions obtained by other optimization codes. It has been observed that this code is robust: it has solved a variety of problems from different starting points. However, the code is inefficient in that it takes considerable CPU time as compared with certain other available codes. Further work is required to improve its efficiency while retaining its robustness. Author

THE DEVELOPMENT OF STRESS INTENSITY FACTORS

D. P. Rooke Aug. 1993 36 p Presented at the International Conference on Fretting Fatigue, Sheffield, England, 19-22 Apr. 1993
(DRA-TR-93057; ICAF-1948) Avail: CASI HC A03/MF A01

Cracks are costly: their presence increases the time and effort spent on maintenance and repair and they may ultimately lead to component fracture and subsequent structural failure, which in extreme cases can endanger human life. A US National Committee estimated that the cost of fracture amounted to as much as 4 percent of the gross National Product: it is therefore imperative to try and reduce these effects. Since cracks cannot be eliminated, procedures must be devised to quantify and predict the behavior of cracked structures under service conditions. The cracks, themselves, may be present as small flaws in the material manufacturing stage; they may arise during fabrication; or they may be the result of damage (fatigue, impact, corrosion etc.) to the completed structure. Systematic scientific rules must be devised to characterize cracks and their effects and to predict if and when they may become unsafe during the structures operational service life. This science has come to be called Fracture Mechanics and the prime characterization and prediction parameter is the stress intensity factor. This report outlines the sources and theoretical methods for obtaining stress intensity factors for a wide range of structural configurations in both two and three dimensions. Author (revised)

FLAT RECTANGULAR ORTHOTROPIC PLATES UNDER UNIFORMLY DISTRIBUTED NORMAL PRESSURE. ELASTIC STRESSES AND DEFLECTIONS FOR VARIOUS FORMS OF EDGE RESTRAINT

Feb. 1994 30 p
(ISSN 0141-4097; ISSN 0958-0360)
(ESDU-93011; ISBN-0-85679-863-0) Avail: ESDU

ESDU 93011 introduces a Fortran program which gives (1) the detailed distribution of deflection and either the moments and in-plane forces, or the stresses, or the strains, throughout the plate for a given pressure load or (2) the maximum deflection and the peak values of moments, forces, stresses and strains and their location for a range of pressure loads. The differential equations formed in terms of stress and displacement functions apply to elastic, large deflection, moderate rotation, thin plate theory and are solved by a finite difference technique for edge conditions of elastic rotation, translation or shear restraint. The plate must be specially-orthotropic, is considered homogeneous, is rigidly restrained in its own plane, and its properties are input as in-plane and flexural stiffness matrices. The plate is treated as symmetrical and so behavior in one quarter only is considered with a grid chosen by the user of 4x4, 6x6 or 8x8 points. Output of the distributions can be chosen to be at every point or at alternate points. The program input and output are fully described, error messages that may be output are explained, and a worked example illustrates its use. The program is available on disc (uncompiled) in the software volume as ESDUpac A9311. ESDU

THREE-DIMENSIONAL ELASTIC STRESS CONCENTRATION FACTORS: PLAIN OR COUNTERSUNK HOLE IN A WIDE PLATE SUBJECTED TO TENSION, BENDING, OR PIN LOADING

Dec. 1993 16 p
(ISSN 0141-4089; ISSN 0144-2805; ISSN 0958-0379; ISSN 0141-4097)
(ESDU-93030; ISBN-0-85679-883-5) Avail: ESDU

ESDU 93030 introduces a Fortran program, ESDUpac A9330, that calculates the stress concentration factors from polynomial equations that were fitted to a wide range of finite element calculations and reproduces them within two percent. For plain and countersunk holes, stresses due to remote tension and out-of-plane bending are considered. In addition, for plain holes the effect of pin loading is simulated by a cosine pressure distribution constant through the plate thickness and unaffected by any distortion. For countersunk holes, the ratio of shank length to plate thickness can vary from 0 to 1 (pure conical hole to constant diameter hole) and for both hole types the diameter-to-plate thickness can vary from 0.5 to 5. The program is provided on disk (uncompiled) in the software volume and compiled within ESDUview, a user-friendly shell running under MS-DOS that prompts on screen for input data. A worked example shows the format of the input and output data; the latter gives stress concentration values at 21 equally-spaced positions along the bore, and maximum and minimum values with their exact locations. Graphs illustrate the effect of varying the major parameters on the distribution of stress along the bore. Comparison of the results with other available data is made. ESDU

N94-28145 ESDU International Ltd., London (England).

FATIGUE PROPAGATION BEHAVIOUR OF SHORT CRACKS (1-2 mm) IN STEELS

Dec. 1993 57 p
(ISSN 0141-4089; ISSN 0958-0387)
(ESDU-93033; ISBN-0-85679-886-X) Avail: ESDU

ESDU 93033 presents data that compare the behavior of long and short cracks which are longer than the typical microstructural dimension but are not substantially larger than the radius of the plastic zone at the crack tip. Experimental data extracted from the literature for crack growth rate under constant amplitude loading are presented graphically against stress intensity factor range for both long and short cracks at various stress ratios in air for AISI 4340, HY 130, AISI 1045, SAE 0030 (UNS J 03010), and AISI 1020. In addition, there are data obtained in vacuum for E460, and in salt solution and sea water for HY 130. Data in air for E460, A508, QIN, and 304 are for only one stress ratio (but include the effect of sea water for QIN). Data for AISI 316 are for short cracks only in air at two stress ratios and for EN5 are for short and long cracks in sea water and one stress ratio only. No consistent relationship between yield strength and either short or long crack growth behavior was found, but where a short crack effect was evident the threshold value of stress intensity factor range was lower than for long cracks, and the crack growth rate at low values of stress intensity factor range was greater. HIGH-PERFORMANCE PARALLEL ANALYSIS OF COUPLED PROBLEMS FOR AIRCRAFT PROPULSION Final Report

C. A. Felippa, C. Farhat, S. Lanteri, U. Gumaste, and M. Ronaghi Mar. 1994 38 p
(Grant NAG3-1273; RTOP 505-10-11)
(NASA-CR-195292; E-8658; NAS 1.26:195292; CU-CSSC-93-16) Avail: CASI HC A03/MF A01

Applications are described of high-performance parallel, computation for the analysis of complete jet engines, considering its multi-discipline coupled problem. The coupled problem involves interaction of structures with gas dynamics, heat conduction and heat transfer in aircraft engines. The methodology issues addressed include: consistent discrete formulation of coupled problems with emphasis on coupling phenomena; effect of partitioning strategies, augmentation and temporal solution procedures; sensitivity of response to problem parameters; and methods for interfacing multiscale discretizations in different single fields. The computer implementation issues addressed include: parallel treatment of coupled systems; domain decomposition and mesh partitioning strategies; data representation in object-oriented form and mapping to hardware driven representation, and tradeoff studies between partitioning schemes and fully coupled treatment. A REVIEW OF RECENT AEROELASTIC ANALYSIS METHODS FOR PROPULSION AT NASA LEWIS RESEARCH CENTER

T. S. R. Reddy (Toledo Univ., OH.), Milind A. Bakhle (Toledo Univ., OH.), R. Srivastava (Toledo Univ., OH.), Oral Mehmed, and George L. Stefko Sep. 1993 25 p
(Grants NAG3-1137; NAG3-1234; NAG3-1230; RTOP 535-03-01; RTOP 505-63-5B)
(NASA-TP-3406; E-7535; NAS 1.60:3406) Avail: CASI HC A03/MF A01

This report reviews aeroelastic analyses for propulsion components (propfans, compressors and turbines) being developed and used at NASA LeRC. These aeroelastic analyses include both structural and aerodynamic models. The structural models include a typical section, a beam (with and without disk flexibility), and a finite-element blade model (with plate bending elements). The aerodynamic models are based on the solution of equations ranging from the two-dimensional linear potential equation to the three-dimensional Euler equations for multibladed configurations. Typical calculated results are presented for each aeroelastic model. Suggestions for further research are made. Many of the currently available aeroelastic models and analysis methods are being incorporated in a unified computer program, APPLE (Aeroelasticity Program for Propulsion at LEwis). Author (revised)

ANALYSIS AND CONTROL OF HOURGLASS INSTABILITIES IN UNDERINTEGRATED LINEAR AND NONLINEAR ELASTICITY Final Report

Olivier P. Jacquotte and J. Tinsley Oden Mar. 1994 127 p
(Grant NAG3-329; RTOP 509-10-11)
(NASA-CR-195293; E-8659; NAS 1.26:195293; TICOM-85-10) Avail: CASI HC A07/MF A02

Methods are described to identify and correct a bad finite element approximation of the governing operator obtained when under-integration is used in numerical code for several model problems: the Poisson problem, the linear elasticity problem, and for problems in the nonlinear theory of elasticity. For each of these problems, the reason for the occurrence of instabilities is given, a way to control or eliminate them is presented, and theorems of existence, uniqueness, and convergence for the given methods are established. Finally, numerical results are included which illustrate the theory. Author (revised)

THE POTENTIAL FOR THE DEPARTMENT OF DEFENSE TO USE SPACE-BASED REMOTE SENSING TO SUPPORT DOD AND OTHER GOVERNMENT AGENCIES' ENVIRONMENTAL PROGRAMS
Donald R. Artis, Jr. Dec. 1993 11 p
(AD-A273895; TEC-R-198) Avail: CASI HC A03/MF A01

This paper describes the potential for the Department of Defense (DoD) to support other Government agencies in the management of national and worldwide environmental programs while continuing to conduct the traditional role of DoD as the military arm of the Federal Government. The DOD space-based remote sensing program must complement other programs, rather than replace or duplicate those programs. This may include defense-related remote sensing applying technologies to civil applications and environmental functions and ecological information needs; using DoD sensors for civil applications; and expanding the role of the Environmental Task Force (ETF). DTIC

OBJECTIVE IMAGE QUALITY METRICS: APPLICATIONS FOR PARTIALLY COMPENSATED IMAGES OF SPACE OBJECTS M.S. Thesis
David J. Lee Dec. 1993 90 p
(AD-A273837; AFIT/GSO/ENP/93D-03) Avail: CASI HC A05/MF A01

Digital image reconstruction tasks currently require human intervention for a subjective evaluation of image quality. A method for unsupervised measurement of digital image quality is desired. This research investigated various parameters (metrics) that can be automatically extracted from a digital image and tested how well they correlated with image quality. Specifically, images of orbiting satellites captured by a partially compensated adaptive optics telescope were dealt with. Two different types of quantities were investigated: (1) Fourier spectral parameters, based on the spatial-frequency sensitivities of the HVS; and (2) Histogram shape parameters (i.e., image statistical moments) giving quantitative insight into the structural content, information content, and brightness distribution of an image. An atmospheric imaging simulator was used to generate a test database of images. The use of simulated imagery allowed precise control of the imaging parameters directly relating to image quality: (1) Root Mean Square Error; (2) Seeing conditions (Fried Parameter, ro); and (3) Target magnitude. This in turn allowed quantitative testing of candidate image quality metrics. Metrics could also be tested against the user defined parameters of the reconstruction process, as a proof-of-concept for totally unsupervised image reconstruction. Finally, based on tnis testing, two successful image quality metrics are recommended. DTIC

GEOID DETERMINATION: WITH HELP OF THE ALTERNATIVE SCATTERING METHOD Thesis [GEOIDEBEPALING: MET BEHULP VAN EEN ALTERNATIEVE SCHATTINGSMETHODE]
Mario G. Burger Feb. 1993 97 p In DUTCH
(ETN-94-95375) Avail: CASI HC A05/MF A02

Use of the Stokes formula and the least squares collocation method for geoid height determination is addressed, and an alternative method proposed by R. Rummel (1982) with the purpose of combining the advantages of the first two methods while eliminating the disadvantages is investigated. The alternative method has three important components: derivation of the so called global estimator that must be seen as the limiting case of the collocation; the derived estimator must be evaluated by a numerical integration (discretization); the numerical investigation. From the test calculations realized, the following conclusions can be made. A partially applied alternative method gives similar results to those of the classical Stokes method where the surface weights are given by block anomalies with mean gravity. The more unregularly distributed the points are, the bigger the differences between the treated triangulations get. This means that the differences in surface weights will grow as well, leading to different geoid heights. At regularly distributed points the triangulations are almost identical and the calculation of the weights becomes independent of the chosen triangulation method. In the innermost zone, integration has to be made over the surface assigned to each gravity anomaly. ESA

GEOMETRIC CORRECTION OF SPOT IMAGES WITH USE OF DIGITAL ELEVATION MODELS Thesis [GEOMETRISCH CORRECTIE VAN SPOT-BEELDEN MET BEHULP VAN DIGITALE HOOGTE MODELLEN]
Ron Oosterwijk Aug. 1992 105 p In DUTCH
(ETN-94-95033) Avail: CASI HC A06/MF A02

Modeling and eliminating of distortions caused by not taking into account relief and the geometrical correction of SPOT images are addressed. Resulting from these corrections is an image which is an orthogonal projection of the terrain on a reference system. This orthogonal projection is called an ORTHO-image. A method which uses multispectral SPOT images with a resolution of 20 by 20 m and Digital Elevation Models (DEM's) with a spatial resolution of approximately 100 by 100 m is presented. The reference system used is UTM (Universal Transversal Mercator) projection. The results could only be visually inspected due to the absence of control and checkpoints. The effects of the relief correction are clearly made visible with specially constructed composite grid images by comparing a system corrected image with an ORTHO-image. A stereocouple is generated consisting of a system corrected image and an ORTHO-image. This stereocouple shows an excellent view of the relief. ESA

DIFFERENTIATING THE ROLE OF LAND SURFACE VARIABILITY AND CLOUDINESS VARIABILITY ON GLOBAL ENERGY TRANSPORT WITHIN THE ATMOSPHERE AND OCEANS Final Report
Eric A. Smith Mar. 1993 8 p
(Grant NAGw-1840)
(NASA-CR-195229; NAS 1.26:195229) Avail: CASI HC A02/MF A01

The following provides the final report on NASA IDP Project NAGW-1840 'Differentiating the Role of Land Surface Variability on Global Energy Transport within the Atmosphere and Oceans'. The project was designed to investigate the role of regional perturbations in the earth radiation budget on atmospheric and oceanic energy transports on an interannual basis. We proposed a modeling strategy based on an entropy extremum principle that could be used to separate the transports into oceanic and atmospheric components so as to better understand the effects of regional perturbations at the distinct atmospheric and oceanic time scales. The original focus was to consider the maintenance and year-to-year modulation of a large-scale, low-latitude North African-West Pacific Ocean net radiation dipole, which we had detected in the Nimbus 6 and 7 record of earth radiation budget measurements, and which necessitated significant cross-meridional energy transports to maintain global equilibrium. In addition, perturbations in the radiation balance term were to be partitioned into cloud-induced and surface-induced components to better understand the feedbacks between clouds and surface boundary conditions on interannual variability of the radiation balance. REMOTE SENSING AND GIS FOR THE MANAGEMENT AND INVESTIGATION OF THE WADDEN SEA [REMOTE SENSING EN GIS TEN BEHOEVE VAN HET BEHEER VAN EN ONDERZOEK IN DE WADDENZEE]
J. vandenBerg (Rijkswaterstaat Dienst Getijdewateren, The Hague, Netherlands.) and A. J. deLeeuw (Rijkswaterstaat Dienst Getijdewateren, The Hague, Netherlands.) Jan. 1993 25 p In DUTCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(BCRS-92-20; ISBN-9-05-411062-7; ETN-94-94821) Avail: CASI HC A03

The use of Remote Sensing (RS) techniques combined with GIS (Geographic Information Systems) for the operational management of the wet part of the Wadden Sea was investigated. The available RS and GIS techniques, data and applications, as well as the possible management problems where RS and GIS techniques can be useful, are reviewed. A proposal for the sequence of the project is given, including a time schedule and cost estimates. The applicability of RS in the Wadden water is limited. The large scale of the Wadden region favorizes RS recording techniques.

The use of GIS has already started with the development of the WADGIS demonstration model for the Dutch Wadden Sea and the WAT is for the German Wadden region. ESA

(NASA-CR-195227; NAS 1.26:195227) Avail: CASI HC A03/MF A01

Given the focus on global change and the attendant scope of such research, we anticipate significant growth of requirements for investigator interaction, processing system capabilities, and availability of data sets. The increased complexity of global processes requires interdisciplinary teams to address them; the investigators will need to interact on a regular basis; however, it is unlikely that a single institution will house sufficient investigators with the required breadth of skills. The complexity of the computations may also require resources beyond those located within a single institution; this lack of sufficient computational resources leads to a distributed system located at geographically dispersed institutions. Finally the combination of long term data sets like the Pathfinder datasets and the data to be gathered by new generations of satellites such as SeaWiFS and MODIS-N yield extra-ordinarily large amounts of data. All of these factors combine to increase demands on the communications facilities available; the demands are generating requirements for highly flexible, high capacity networks. We have been examining the applicability of the Advanced Communications Technology Satellite (ACTS) to address the scientific, computational, and, primarily, communications questions resulting from global change research. As part of this effort three scenarios for oceanographic use of ACTS have been developed; a full discussion of this is contained in Appendix B. Author

(VTT-JULK-772; ISBN-951-38-4120-0; ETN-94-95244) Copyright Avail: CASI HC A05/MF A01

An image correlation method for finding the control points required for satellite image correction is presented. Different methods of correlation are reviewed, focusing on feature based methods. The feature based correlation method developed is described with examples. The method is concluded to be at least as accurate as the traditional manual solution, but gives many more control points in shorter time lapse. It is equally reliable in circumstances where only the data transmitted simultaneously with the image is available. ESA

SIMA: A MODEL FOR FOREST SUCCESSION BASED ON THE CARBON AND NITROGEN CYCLES WITH APPLICATION TO SILVICULTURAL MANAGEMENT OF THE FOREST ECOSYSTEM
Seppo Kellomaeki, Hannu Vaeisaenen, Heikki Haenninen, Taneli Kolstroem, Risto Lauhanen, Ulla Mattila, and Brita Pajari 1992 90 p
(ISSN 0780-8232)
(Silva-Carelica-22; ISBN-951-708-060-3; ETN-94-95270) Avail: CASI HC A05/MF A01

A model for succession in the forest ecosystem is described. The growth and development of trees and ground cover are controlled by temperature and light conditions and the availability of nitrogen and water. In addition, the effects of the annual cycle of trees, wild fire, and windblow are included in the model as factors which control the survival and productivity of trees. The model makes it also possible to evaluate the risk of insect attack assuming that the risk of insect attack is inversely related to the growth efficiency of trees. ESA

A COMPARATIVE EVALUATION OF SAR AND SLAR
G. A. Mastin, J. J. Manson, J. D. Bradley, R. M. Axline, and G. L. Hover 1993 11 p Presented at the 2nd Thematic Conference on Remote Sensing for Marine and Coastal Environments, New Orleans, LA, 31 Jan. - 2 Feb. 1994
(Contract DE-AC04-94AL-85000)
(DE94-002922; SAND-93-2616C; CONF-940123-1) Avail: CASI HC A03/MF A01

Synthetic aperture radar (SAR) was evaluated as a potential technological improvement over the Coast Guard's existing side-looking airborne radar (SLAR) for oil-spill surveillance applications. The US Coast Guard Research and Development Center (R&D Center), Environmental Branch, sponsored a joint experiment including the US Coast Guard, Sandia National Laboratories, and the Naval Oceanographic and Atmospheric Administration (NOAA), Hazardous Materials Division. Radar imaging missions were flown on six days over the coastal waters off Santa Barbara, CA, where there are constant natural seeps of oil. Both the Coast Guard SLAR and the Sandia National Laboratories SAR were employed to acquire simultaneous images of oil slicks and other natural sea surface features that impact oil-spill interpretation. Surface truth and other environmental data were also recorded during the experiment. The experiment data were processed at Sandia National Laboratories and delivered to the R&D Center on a computer workstation for analysis by experiment participants. Issues such as optimal spatial resolution, single-look vs. multi-look SAR imaging, and the utility of SAR for oil-spill analysis were addressed. Finally, conceptual design requirements for a possible future Coast Guard SAR were outlined and evaluated. DOE

OPTIMIZATION OF VECTOR PRODUCT FORMAT (VPF) DATA FOR MAP BACKGROUND DISPLAY IN ARMY TACTICAL SYSTEMS
William Kannawin and Karl Koklauner Jan. 1994 14 p
(AD-A274687; USATEC-R-205) Avail: CASI HC A03/MF A01

The U.S. Army currently relies on raster products as source data for map background displays in tactical systems. In the future, The Defense Mapping Agency would prefer to support these requirements with vector products to reduce production costs and take better advantage of their new Digital Production System. Creative and innovative solutions are needed to allow map-like symbolized displays to be generated on current generation computers, within acceptable time tolerances, using vector source data. Science Applications International Corporation (SAIC) under contract with the U.S. Army Topographic Engineering Center (TEC) has demonstrated that this can be done effectively using special indexing techniques. CONSTRUCTION AND APPLICATIONS OF THE TWO DIMENSIONAL DELAUNAY TRIANGULATED IRREGULAR NETWORK AND THE THREE DIMENSIONAL DELAUNAY TETRAHEDRON MODEL Thesis [CONSTRUCTIE EN TOEPASSINGEN VAN HET 2-DIMENSIONALE DELAUNAY DRIEHOEKSMODEL EN HET 3-DIMENSIONALE DELAUNAY TETRAEDERMODEL]
Edward Verbree Aug. 1992 73 p In DUTCH
(ETN-94-95034) Avail: CASI HC A04/MF A01

Two topological models are presented: the two dimensional Triangulated Irregular Network (2D-TIN) and the tetrahedron model (3D-TIN). These models have several advantages with respect to the regular grid structured terrain model. In the Delaunay 2D-TIN model the triangles are as equilateral as possible; for a good visualization sharp triangles are avoided. The program P2DTIN constructs the Delaunay model according to the boundary conditions. Several applications of the model are outlined. The tetrahedron model overcomes the restriction that the terrain points have to be univocally projected in a plane. The program P3DTIN constructs such a model starting from a set of three dimensional data points. A number of applications are given. ESA

Research was conducted to determine whether airborne multispectral data acquired using an imaging spectrometer can be used for accurate mapping of the vegetation and substrates in the intertidal and nearshore environments. The imaging spectrometer used in the study allows the user to tailor the spectral bandwidths of the instrument to the spectral properties of the physical and biological features under study. The spectral characteristics of the intertidal environment are examined and an eight-channel bandset is designed that allows insight into certain phenomena or processes that are only evident in narrow spectral ranges. Previous coastal remote sensing studies are reviewed and the data collection methodology is described along with the evaluation, classification, and accuracy assessment of imagery obtained on Vancouver Island, British Columbia. Radiance plots, between-band correlations, and a principal components analysis were used to examine two physically and biologically distinct littoral regions. Five of the eight bands were found to contribute significant unique information pertaining to intertidal vegetation and substrate identification. Classification of these bands showed that different substrates and algal genera could be identified, and spectrally similar green algae could be differentiated. Author (CISTI)

AN EVALUATION OF AN AIRBORNE REMOTE SENSING SYSTEM USED TO DETERMINE ICE THICKNESS AND GEOMETRY OF A FIRST YEAR SEA ICE RIDGE LOCATED IN THE BEAUFORT SEA M.S. Thesis

Robert Bowen 1993 209 p

(ISBN-0-315-84383-7; CTN-94-61027) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

One- and two-dimensional interpretation techniques were applied to the electromagnetic (EM) anomalies obtained from a state of the art airborne remote sensing system field tested over a first-year ice ridge. This airborne system combines the technology of a laser altimeter, an impulse radar and an electromagnetic induction sounding system in an attempt to measure irregular ice geometry accurately. The EM component of the airborne system is evaluated based on a volumetric comparison of the airborne EM interpreted data with extensive ground truth data obtained from submersible sonar surveys and surface theodolite surveys. The overall form of the ridge geometry at the study site was obtained by generating digital terrain models from the ground truth data. Two interpolation routines were used, both yielding similar form and volumetric results. Comparison of the ground truth data with the EM interpreted data indicate that the interpretation techniques poorly resolve ice feature definition. However, raw EM anomalies records overlaid onto appropriate cross sections of the ridge suggest that the resolution of the system is far better than the interpreted data would suggest. RESPONSE OF AN AIRBORNE SYNTHETIC APERTURE RADAR TO SEA ICE IN THE MARGINAL ICE ZONE Ph.D. Thesis

Michael John Collins May 1993 207 p

(ISBN-0-315-84243-1; CTN-94-61028) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Theory on statistical scattering from rough surfaces and synthetic aperture radar (SAR) imaging is reviewed and a theoretical model is developed for a particular measure of image texture, the autocorrelation function (ACF). It is proposed that SAR intensity images of sea ice are spatially non-Gaussian, and that the predominant types and forms of marginal ice zone (MIZ) sea ice may be discriminated based on estimated ACF model parameters. Experimental data were collected from the Labrador MIZ, with the primary data set being SAR imagery collected from an airborne platform at two frequencies (5.3 and 9.25 GHz) and four polarizations. To verify the theoretical foundations of the ACF model, imaging system basis experiments measured system focus, examined its effect on image texture, and verified the derived system impulse response. Scattering basis experiments examined speckle development and the extent of non-Gaussian image texture. The model was found to provide an excellent fit to measured ACFs. The parameter measuring non-Gaussian image texture agreed with the scattering basis experiments. The image texture was found to depend on the form of the sea ice as much as its type. For a given type, the various forms could be discriminated with single SAR channels; for full discrimination of all types and forms, a two-channel combination was necessary. Author (CISTI)

DIGITAL FILTER DESIGN FOR SENSOR SIMULATION: APPLICATION TO THE BRAZILIAN REMOTE SENSING SATELLITE

Gerald Jean Francis Banon and Ailton Cruz dosSantos Oct. 1993 52 p

(INPE-5523-RPQ/665) Avail: CASI HC A04/MF A01

A model of the interaction between a large-field-of-view low-resolution sensor on board an earth observation satellite and the earth surface is presented. The simulated sensor is obtained through the composition of a digital simulation algorithm by a smaller field-of-view and higher resolution sensor. A new digital filter design technique is proposed to approximate an ideal Gaussian filter. The resulting filter can be implemented on any existing image processing platform. Finally, two image patches as they would be produced by the SSR (Remote Sensing Satellite) of MECB (Brazilian Complete Spatial Mission) from a LANDSAT-TM (Thematic Mapper) scene are presented as an example. TRAPEZOID-ORIENTED COMPRESSION OF RUN LENGTH CODED MAP DATA

Daniel Joensson and Erland Jungert Apr. 1993 45 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB94-123312; FOA-C-30711-3.4) Avail: CASI HC A03

The method for compressing a set of Run Length Code (RLC) items described here is called Generalized Sequential Trapezoids (GST). It is part of an optimization process with the objective to minimize the size of a spatial database intended for a Geographical Information System (GIS). A major advantage of the proposed method, apart from the extensive saving of space, is the scale independence of the representation. The main concern of this work is the general aspects of the structure. Other aspects such as speed of the algorithms and other performance measures are disregarded, as well as the efficiency and space requirements of the internal representation. The new representation is usable for the same applications as the RLC structure, with only a few modifications. NTIS

We present a class of S-unimodal maps having an invariant measure which is absolutely continuous with respect to Lebesgue measure. This measure can often be proved to be finite. We give an example of a map which has such a finite measure and for which the liminf of the derivatives of the iterates of the map in the critical value is finite. It will be shown that all topologically conjugate non-flat S-unimodal maps have these same properties. NTIS

CONIFER TREE INFLUENCE ON DIGITAL TERRAIN ELEVATION DATA (DTED): A CASE STUDY AT DULLES INTERNATIONAL AIRPORT Final Report, Mar. - Aug. 1991

Kevin R. Slocum Sep. 1993 27 p

(AD-A274213; TEC-0038) Avail: CASI HC A03/MF A01

Conifer tree influence on the collection and portrayal of Digital Terrain Elevation Data (DTED) is presented. Study sites are investigated which had dense conifer canopy closure. Two separate DTED collection techniques are examined in the context of studying conifer tree influence: (1) photo source auto-correlated, and (2) photo source operator assisted (floating dot). Field surveying is the mechanism used for collecting accurate, verifiable ground elevation data subsequently compared against the elevations of corresponding DTED positions. Estimated conifer tree stand heights (at the time of DTED photo source) are compared against the difference in value between DTED and field surveyed elevations. A close relationship between stand height and difference values demonstrates the potential for conifer tree height inclusion within DTED 'ground' elevations. Terrain modelling impacts caused by the addition of tree heights within the DTED are addressed. DTIC

Forest assessment activities being carried out in remote sensing laboratories around the world are addressed. The use of satellite imagery in these assessments is focused upon. The status of tropical forest resources is examined. The use of data from NOAA/AVHRR (advanced very high resolution radiometer) is compared to that from LANDSAT thematic mapper and SPOT. The application of geographic information systems (GIS) is also considered. Different methods of processing the data and analyzing the satellite images are considered. Particular emphasis is given to the mapping of closed tropical forest cover in west Africa using NOAA/AVHRR-local area coverage (LAC), and the analysis of LANDSAT images to assess the changes in woody biomass density in the Tendelti area of central Sudan. For individual titles, see N94-27183 through N94-27185.

Key concepts such as tropical forests, deforestation, and forest degradation are defined. Objectives in global assessments are considered. The status of tropical forest resources is examined. The development of remote sensing methodology for tropical forest assessments is discussed. The remote sensing methodology for global forest cover assessments is largely based on NOAA/AVHRR (advanced very high resolution radiometer). The two interrelated branches of methodology are mapping and monitoring. The potential of the methodology discussed is now being recognized in the international debate on tropical forest issues. Many have realized than an objective record of forest cover at a single moment in time was impossible until the advent of satellite imagery. A number of remote sensing oriented projects dedicated to tropical forest assessment at global and continental scales are summarized. The status in 1991 of the following regions is assessed: South America, west Africa, central Africa, and south-east Asia. Experience gained in forest cover asessment projects in the tropical zone using digital AVHRR data analysis is summarized. A case study of a geographic information system (GIS) application is presented. The compilation of a global tropical forest cover map is considered. Problems remaining to be solved in the remote sensing of deforestation are addressed. ESA

MAPPING CLOSED TROPICAL FOREST COVER IN WEST AFRICA USING NOAA/AVHRR-LAC DATA
Risto Paeivinen, Juho Pitkaenen, and Ron Witt (United Nations Environment Programme, Geneva, Switzerland.) *In* Joensuu Univ., Assessment of Tropical Forests Using Satellite Data Jan. 1992 p 27-52 (For primary document see N94-27182 07-43)
Copyright Avail: CASI HC A03/MF A02

A project to map the remaining closed tropical forest cover in west Africa is reported. The major purpose of the project is the use of one kilometer NOAA satellite data from the advanced very high resolution radiometer (AVHRR) sensor local area coverage (LAC) for mapping forested and non-forested regions, and other broad vegetation categories, within the humid tropical forest zone of west Africa. The results were compared with high resolution satellite data from LANDSAT and SPOT, which in turn had been classified using information obtained in field visits. The best results for mapping closed tropical forest (more than 40 percent canopy cover) versus surrounding vegetation classes were obtained using a supervised classification and a segmented approach to mapping across the AVHRR scenes used. A total of four scenes were used to produce a map of closed tropical forest cover in west Africa. ESA

WOODY BIOMASS DENSITY IN THE TENDELTI AREA OF THE CENTRAL SUDAN
T. Pukkala, V. Pohjonen, and E. Muinonen *In its* Assessment of Tropical Forests Using Satellite Data Jan. 1992 p 53-92 (For primary document see N94-27182 07-43)
Copyright Avail: CASI HC A03/MF A02

Based on LANDSAT images from 1986, 1988, and 1990, changes in the woody biomass density were analyzed in the Tendelti area of central Sudan. Methods based on regression and stratification were compared within three circular areas with 30 km, 18 km, and 3 km radii, centered on a town or a big village. The method based on regression used the normalized difference vegetation index as a predictor of woody biomass. In the other method, the images were stratified by the maximum likelihood technique, and the woody biomass densities for each class were measured in the field by sampling with circular plots. The study areas included bare sand dunes, moister clay areas with and without tree cover, natural Acacia senegal vegetation on the dunes, and some planted Prosopis juliflora stands. In the two largest circles, no temporal changes in the woody biomass were detected between the three time points. Inside the smallest circle the woody biomass density doubled between 1988 and 1990, due to succcessful establishment of Prosopis plantations. The average woody biomass density in the Tendelti area was very low, about 0.7 tons dry mass per hectare, which is only 12 percent of the Sudanese national average. Both methods to utilize successive satellite imagery were feasible for monitoring the success of reforestation, especially with species that remain green during the dry season. ESA

MAPPING OF SEAWATER INTRUSION INTO THE COASTAL AQUIFER OF ISRAEL (THE SEAWATER-FRESHWATER INTERFACE) BY TDEM (TIME DOMAIN ELECTROMAGNETIC) METHOD M.S. Thesis
Amit Ronen Jan. 1991 233 p
(ITN-94-85238) Copyright Avail: Issuing Activity (Tel-Aviv Univ., Exact Sciences Library, Ramat Aviv 69978, Israel)

An extensive TDEM (Time Domain Electromagnetic) survey, which covered almost the whole Mediterranean coastal strip of Israel, was carried out during the summer of 1989 in order to make a quantitative evaluation of the TDEM method in detecting seawater intrusion into the coastal aquifer. To achieve statistical significance of the results, a total of approximately 100 TDEM stations was established, some in close proximity to existing observation wells. In order to realize the most objective evaluation of the TDEM results, respective data interpretation was carried out prior to the use of, or even acquaintance with, any geological or hydrological information from the wells. The two main objects of the survey were as follows: (1) statistical corroboration of an extremely important feature of seawater-bearing aquifers, namely their consistent resistivity values which are completely different from those of any known lithology in the area; and (2) quantitative evaluation of the accuracy level of the TDEM method and assessment of its applicability to solving various hydrological problems. It was found that the resistivity values of the seawater-intruded aquifers vary within a range of 1.1 to 2.9 ohm-meter, whereas low-resistivity lithologies have minimum values of approximately 10 ohm-meter. TRAINING ON ASSESSMENT AND MAPPING OF DEFORESTATION: WFW CONFERENCE, BRAZIL
Tania Maria Sausen 1993 6 p Presented at the Asia Pacific ISY Conference: The Earth in Space, 16-20 Nov. 1992
(INPE-5482-PRE/1781) Avail: CASI HC A02/MF A01

At an ISY Conference on Education and Applications held in Deauville, France, Brazil proposed a training program for assessment and mapping of deforestation in the Pan-Amazonian region. The intent was to train project managers so as to establish and conduct national or regional forest monitoring of the Pan-Amazonian region using remote sensing data. The success of the PRODES deforestation project and the acceptance of the Pan-Amazonian proposal inspired the design of this training course which was extended to cover rain forest regions all over the world. The objective of the course, which was part of the activities of the World Forest Watch Conference held in Sao Jose dos Campos, Sao Paulo State, Brazil, on 27-29 May 1992, was to train project managers in subregion (state and country level) deforestation mapping, assessment, and monitoring by using remote sensing and geographic information system techniques. This paper presents an overview of the course schedule, its participants and training staff, and some of the problems addressed in the course. CASI

MORPHODYNAMICS OF INTER-TIDAL AREAS: THE WADDEN SEA

H. H. S. Noorbergen 21 Aug. 1992 18 p Presented at A Coastal Congress, Kiel, Germany, 7-13 Sep. 1992 Sponsored by Beleidcommissie Remote Sensing, Delft, Netherlands Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(NLR-TP-92356-U; ETN-94-95453) Avail: CASI HC A03

The use of LANDSAT MSS (Multi Spectral Scanner) satellite images in order to determine the geomorphology of the Dutch Wadden Sea at one certain moment is presented. By using more satellite images of different acquisition dates, geomorphological changes can be detected. By 1991, LANDSAT MSS imagery from the whole world was available for two decades. The present database of 20 years of remote sensing data provides a useful potential for multitemporal research. Three mosaics of LANDSAT MSS images were composed, all taken at the same low water levels but of different acquisition years: 1975, 1982, and 1987. After geometric coregistration it was possible to detect morphological changes between these years. Several image processing methods were used: spatial gradient filtering, and three color composition of the three different years. The remote sensing analysis can be considered operational in the sense that well defined basic image processing routines suffice to obtain the information, and that the project satisfies immediate information needs of a large area leading to direct application in hydrological studies and engineering work. SPECTRUM ANALYSIS OF MULTISPECTRAL IMAGERY IN CONJUNCTION WITH WAVELET/KLT DATA COMPRESSION

Jonathan N. Bradley and Christopher M. Brislawn 1993 6 p Presented at the IEEE Asilomar Conference on Signals, Systems, and Computers, Pacific Grove, CA, 1-3 Nov. 1993
(Contract W-7405-eng-36)
(DE94-003961; LA-UR-93-3951; CONF-9311135-2) Avail: CASI HC A02/MF A01

The data analysis program, SPECTRUM, is used for fusion, visualization, and classification of multi-spectral imagery. The raw data used in this study is Landsat Thematic Mapper (TM) 7-channel imagery, with 8 bits of dynamic range per channel. To facilitate data transmission and storage, a compression algorithm is proposed based on spatial wavelet transform coding and KLT decomposition of interchannel spectral vectors, followed by adaptive optimal multiband scalar quantization. The performance of SPECTRUM clustering and visualization is evaluated on compressed multispectral data. 8-bit visualizations of 56-bit data show little visible distortion at 50:1 compression and graceful degradation at higher compression ratios. Two TM images were processed in this experiment: a 1024 x 1024-pixel scene of the region surrounding the Chernobyl power plant, taken a few months before the reactor malfunction, and a 2048 x 2048 image of Moscow and surrounding countryside. ICE SURFACE TEMPERATURE RETRIEVAL FROM AVHRR, ATSR, AND PASSIVE MICROWAVE SATELLITE DATA: ALGORITHM DEVELOPMENT AND APPLICATION Annual Report

Jeff Key, James Maslanik, and Konrad Steffen 23 Mar. 1994 20 p
(Grant NAGw-3437)
(NASA-CR-195276; NAS 1.26:195276) Avail: CASI HC A03/MF A01

One essential parameter used in the estimation of radiative and turbulent heat fluxes from satellite data is surface temperature. Sea and land surface temperature (SST and LST) retrieval algorithms that utilize the thermal infrared portion of the spectrum have been developed, with the degree of success dependent primarily upon the variability of the surface and atmospheric characteristics. However, little effort has been directed to the retrieval of the sea ice surface temperature (IST) in the Arctic and Antarctic pack ice or the ice sheet surface temperature over Antarctica and Greenland. The reason is not one of methodology, but rather our limited knowledge of atmospheric temperature, humidity, and aerosol vertical, spatial and temporal distributions, the microphysical properties of polar clouds, and the spectral characteristics of snow, ice, and water surfaces. Over the open ocean the surface is warm, dark, and relatively homogeneous. This makes SST retrieval, including cloud clearing, a fairly straightforward task. Over the ice, however, the surface within a single satellite pixel is likely to be highly heterogeneous, a mixture of ice of various thicknesses, open water, and snow cover in the case of sea ice. Additionally, the Arctic is cloudy - very cloudy - with typical cloud cover amounts ranging from 60-90 percent. There are few observations of cloud cover amounts over Antarctica. The goal of this research is to increase our knowledge of surface temperature patterns and magnitudes in both polar regions, by examining existing data and improving our ability to use satellite data as a monitoring tool. Four instruments are of interest in this study: the AVHRR, ATSR, SMMR, and SSM/I. Our objectives are as follows. Retine the existing AVHRR retrieval algorithm defined in Key and Haefliger (1992; hereafter KH92) and applied elsewhere. Develop a method for IST retrieval from ATSR data similar to the one used for SST. Further investigate the possibility of estimating surface temperature from passive microwave data (in conjunction with AVHRR clear sky samples) through the use of 'effective emissivities' and physical relationships between skin temperature and subsurface temperature. Use the general method outlined in MK93 to calculate a 12-year record of clear sky equivalent surface temperatures, or possibly all-sky snow-ice interface physical temperatures, from SMMR and SSM/I, compare these temperatures to climatologies, ECMWF modeled surface temperatures, and surface temperatures predicted by a 2-D ice model. And intercompare several ice surface retrieval methods and validate them against ground measurements from the Swiss Camp on the Greenland ice sheet. Additionally, we intend to develop a surface temperature product based on AVHRR data and possibly blended with drifting buoy and meteorological station temperatures. Derived from text

MULTISPECTRAL AND TEXTURAL CLASSIFICATIONS OF A SPOT HRV-1 IMAGE, REGION OF SHERBROOKE, QUEBEC, CANADA M.S. Thesis [CLASSIFICATIONS MULTISPECTRALE ET TEXTURALE D'UNE IMAGE S.P.O.T. HRV.1 REGION DE SHERBROOKE, QUEBEC, CANADA]

Thierry Baulu Nov. 1993 76 p In FRENCH
(ISBN-0-315-84978-9; CTN-94-61112) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A new method of analyzing multispectral SPOT satellite images of urban areas is presented. A panchromatic and a multispectral image were acquired from the SPOT HRV-1 detector for the area of Sherbrooke, Quebec. A new non-directed classification algorithm developed by Wang et al. was applied to the image, with the sole variable to specify being the final number (k) of classes desired. A number of classifications were carried out by introducing different values of k in order to evaluate the performance of the algorithm. The algorithm was applied to three multispectral channels of the image. In a second step, a textural analysis was conducted to improve the results obtained in the first step. The gray level of each pixel was replaced by the unit value of the corresponding texture. Using a variable magnitude mobile window, the spectrum of textures assigned to the central pixel of this window was constructed. The rest of the image was then swept while basing the classification on the distance established between each dynamic spectral cloud. Data from the two steps were integrated to produce a final classification. The bands from the first two steps were added to subdivide, according to texture, the classes obtained during the multispectral classification. CISTI

FRACTALS AND THEIR APPLICATIONS TO REMOTE SENSING AND DIGITAL MAPPING M.S. Thesis

Mark Phillips Jun. 1990 142 p
(ISBN-0-315-59469-1; CTN-94-60989) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The basic concepts and properties of fractals are reviewed. Insight is provided into various types of fractals and how they are constructed, implemented, and applied. It is then seen how fractals can be applied specifically to remote sensing and digital mapping by examining existing algorithms and techniques, as well as by presenting some original ideas, suggestions, and proposals. For the purpose of this report, remote sensing is considered to mean the electromagnetic remote sensing via satellite of earth resources, and the subsequent operations performed on the acquired imagery. The remote sensing applications covered include digital image compression, evaluation of digital image magnification techniques, and analysis of digital images. Map symbolization through the use of fractals is proposed, namely the use of realistic fractal perspective images to supplement normal map symbols and the use of fractal symbols to denote feature attribute values. Finally, the fractal interpolation and generalization of cartographic linear and surface features is described. Existing algorithms are discussed and reviewed, and an algorithm is proposed for the fractal generalization of surfaces. The proposed method is implemented on fractally simulated terrain surfaces. THE VALIDATION OF ATSR MEASUREMENTS WITH IN SITU SEA TEMPERATURES

P. J. Minnett and K. L. Stansfield (State Univ. of New York, Stony Brook.) Oct. 1993 6 p Presented at the 2nd ERS Symposium on Space at the Service of Our Environment, Hamburg, Germany, 11-14 Oct. 1993
(Contract DE-AC02-76CH-00016)
(DE94-003195; BNL-49690; CONF-9310231-1) Avail: CASI HC A02/MF A01

The largest source of uncertainty in the retrieval of SST (sea-surface) temperature from space-borne infrared radiometric measurements is in the correction for the effects of the intervening atmosphere. During a research cruise of the R/V Alliance, measurements of sea surface temperature, surface meteorological variables, and surface infrared radiances were taken. SST fields were generated from the ATSR data using pre-launch algorithims derived by the ATSR Instrument Team, and the initial comparison between ATSR measurements and SST taken along the ship's track indicate that the dual-angle atmospheric correction is accurate in mid-latitude conditions. MAPPING OF SOIL HUMIDITY USING C-BAND RADAR IMAGES M.S. Thesis

Huaibin Geng Aug. 1993 92 p
(ISBN-0-315-85076-0; CTN-94-61113) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Synthetic aperture radar (SAR) data were examined as a function of soil moisture and roughness, as well as vegetation cover. Single-look airborne C-band SAR data with three polarizations (HH, VV, and HV) from May 1990 were successfully calibrated using forest lots as a reference target. An analysis of linear regression results shows that radar backscatter strongly depends on soil moisture. The C-HH data show the highest correlation with the soil moisture on bare fields. In this experiment, the soils were in the transition zone from smooth to rough. More importantly, they were relatively uniform between fields and especially within a field. Furthermore, the dynamic range of soil moisture data was relatively low. These factors may combine to reduce the roughness factor for this data set. The roughness was therefore considered as a constant. For mapping soil moisture, the effect of roughness could be ignored. For incidence angles over 45 deg, SAR backscatter over vegetation covered fields was controlled mainly by vegetation conditions. In this case, correlation between radar, data, and moisture was absent. A map of soil moisture distribution was created using the inverse of the regression laws. The accuracy of moisture estimation was 90 percent. Author (CISTI)

ROLE OF REMOTE SENSING IN ENERGY, WATER, AND CARBON CYCLE STUDIES OVER THE AMAZON

Getulio Teixeira Batista and Bruce W. Nelson (Instituto Nacional de Pesquisas da Amazonia, Manaus, Brazil.) 1993 11 p Presented at the 25th International Symposium, Remote Sensing and Global Environmental Change, Graz, Austria, 4-8 Apr. 1993
(INPE-5486-PRE/1786) Avail: CASI HC A03/MF A01

Landsat data have been recorded continuously for the Brazilian Amazon Basin since 1973. Examination of these data in yearly intervals has brought out their value for the following synoptic scale evaluations: quantification of total deforestation and deforestation rates; forest recovery; biomass estimation; water and energy balance; and detection of natural disturbances. Considering the uncertainties involving carbon fluxes from tropical forests, the role of GIS based remote sensing techniques is apparent for improving knowledge of past rates of deforestation, monitoring future forest conversions and getting best sampling and extrapolating approaches for biomass estimations, especially for secondary forests for which there are no data available currently. Models of forest change in response to human interference require a prior characterization of the background noise of natural change. We have found four types of natural change visible over just eight years of TM recording: Large forest fires associated with the 1982/83 El Nifio; natural change in bamboo forests of Acre and SW Amazonas; mortality from anomalous flooding of terra firme forest; and large blowdowns (greater than 30 hectares). Although naturally disturbed areas may offer a unique opportunity for remote sensing studies of 'untouched' forest recover, their ecological impacts are far less important than the anthropogenic activities. This paper reviews several experiments that have explored the use of remote sensing for water, energy, and carbon balance studies of the Amazon Region and discusses several approaches for future experiments designed to understand the role of the Amazon in global climatic change. LANDSCAPE DYNAMICS OF NORTHEASTERN FORESTS Annual Report No. 1

Charles D. Canham, John A. Silander, Jr. (Connecticut Univ., Storrs.), and Daniel L. Civco (Connecticut Univ., Storrs.) 29 Mar. 1994 3 p
(Grant NAGw-3703)
(NASA-CR-195272; NAS 1.26:195272) Avail: CASI HC A01/MF A01

This project involves collaborative research with Stephen W. Pacala and Simon A. Levin of Princeton University to calibrate, test, and analyze models of heterogeneous forested landscapes containing a diverse array of habitats. The project is an extension of previous, NASA-supported research to develop a spatially-explicit model of forest dynamics at the scale of an individual forest stand (hectares to square kilometer spatial scales). That model (SORTIE) has been thoroughly parameterized from field studies in the modal upland environment of western Connecticut. Under our current funding, we are scaling-up the model and parameterizing it for the broad range of upland environments in the region. Our most basic goal is to understand the linkages between stand-level dynamics (as revealed in our previous research) and landscape-level dynamics of forest composition and structure. Sandia has been providing technical leadership on behalf of DOE and CORECT on a working level cooperative program with Mexico on renewable energy (PROCER). As part of this effort, the Sandia Design Assistance Center (DAC) and the solar energy program staff at Instituto de Investigaciones Electricas (IIE) in Cuernavaca, Mexico, recently reached agreement on a framework for mutually beneficial technical collaboration on the monitoring and field evaluation of renewable energy systems in Mexico, particularly village-scale hybrid systems. This trip was made for the purpose of planning the details for the joint installation of a data acquisition system (DAS) on a recently completed PV/Wind/Diesel hybrid system in the village of Xcalac on the Southeast coast of the state of Quintana Roo, Mexico. The DAS installation will be made during the week of March 15, 1993. While in Mexico, discussions were also held with personnel from.the National Autonomous University of Mexico (UNAM) Solar Energy Laboratory and several private sector companies with regard to renewable energy project activities and technical and educational support needs in Mexico. The State of Israel has been a pioneer in solar energy development and utilization since it was founded. In the 50's, solar domestic hot water heaters (DHWS) became commercially available. At the same time, research work was started in different areas of solar energy, which led to more advanced solar systems for additional applications. The presentation includes some details on commercial utilization of solar energy and a brief description of the main R&D projects in industry, universities and research institutes. ISA

The conditions for solar energy utilization in the USSR are not too favorable. Only in the country's southern regions is there sufficient insolation to make solar energy utilization economic. In higher latitudes, only seasonal use of solar energy is reasonable. Up to now, the main application of solar energy has been to produce low-temperature heat for hot water production, drying of agricultural goods, space heating and thermal treatment of concrete. A substantial proportion of the solar heating installations are flat plate solar collectors. The total installed area of solar collectors slightly exceeds 100,000 square meters. The collectors are produced by large- and small-scale industry. Where selective coatings are applied to the absorber plates, black nickel or chromium are the main coating materials. Recently launched new projects aim to develop and produce advanced collectors, with enhanced efficiency and reliability. There has been substantial progress in developing photovoltaic (PV) cells for space applications, but terrestrial application of PV is still in a very early stage. Annual production of PV cells totals about 100 kW, based on mono- or polycrystalline silicon. R&D work on thin-film PV cells is in progress. Work is in progress on the development of automated production lines to manufacture 1 MW/yr of crystalline and amorphous silicon. A 5-MW tower-type demonstration plant, with a circular heliostat field, uses steam as the working fluid. Experience with this plant has revealed several disadvantages, including commonwealth of independent states. ISA

Absorption heat pumps, first developed in the 19th century, have received renewed and growing attention in the past two decades. With the increasing cost of oil and electricity, the particular features of this heat-powered cycle have made it attractive for both residential and industrial applications. Solar-powered temperature boosters are among the applications on which intensive research was conducted. The operation of absorption systems is described and several practical applications are discussed. It surveys recent advances in absorption technology, including the selection of working fluids, cycle improvements and multi-staging, and fundamentals of the combined heat and mass transfer in absorption processes. Many chemical energy problems have a physical chemistry nature connected with chemical kinetics and thermodynamics. In the USSR, the development in this field is associated with the name of N. N. Semenov, who was involved in a large number of fundamental and applied physical chemistry problems. The new Institute of Energy Problems of Chemical Physics of the USSR Academy of Sciences is dealing with some of them. An overview of the Institute's work on radiation applications is presented. Examples of the use of radiation in the power industry (e.g., in coal gasification), tire production, mechanical joints, metal powder production, and sterilization of pharmaceutical products are given. Methods and problems involved in these applications are discussed and the great potential for extensive utilization is demonstrated. ISA

The study and development of liquid-metal magnetohydrodynamics (MHD) in Israel, from 1973 to the present, are reviewed. Following extensive research and evaluation, it was established that the most promising concept for a relatively short development time was the gravitational system, using lead or lead alloys as the magnetohydrodynamic fluid and steam or gases as the working fluid. The Etgar Program, set up to investigate such systems, is comprised of seven segments, of which the first six have been completed; work on the last segment has been started. The segments are as follows: studies of the physical phenomena; development of a universal numerical code for parametric studies and optimization and design of the system; materials studies; development of engineering components; construction and testing of small-scale Etgar-type systems; economic evaluation and comparison with conventional technologies; and development of an industrial demonstration plant. ISA

WAYS TO IMPROVE MHD POWER PLANTS AND PROSPECTS OF THEIR APPLICATION
V. M. Batenin, S. I. Pistchikov, J. N. Sokolov, and E. M. Shelkov *In* Ministry of Energy and Infrastructure, The First Energy Conference: Israel and the Former USSR 15 May 1991 p 135-140 (For primary document see N94-26050 07-44)
Copyright Avail: Issuing Activity (Office of the Chief Scientist, Ministry of Energy and Infrastructure, PO Box 13106, 91130 Jerusalem, Israel)

The characteristics of magnetohydrodynamic (MHD) power plants, their modification possibilities, and their areas of application are analyzed. The analysis is based on the status of available power plants including steam turbine and combined-cycle steam/gas power plants. Conventional MHD power plants, based on existing technical solutions and various novel schemes are discussed. The main directions for improvement of energy conversion efficiency are presented, together with ways to modify MHD systems so as to reduce their capital costs. The conclusion is that MHD power plants could be competitive with most advanced power generation technologies. ISA

Utilization of superconducting technology is greatly influenced by the discovery of the so-called high-temperature superconductors (HTS). This paper considers to what extent there is a need for HTS in up-to-date engineering and to what extent the industry is prepared for practical applications. The work on practical use of superconductors was started about 30 years ago. As a result, two fields of high-current superconductivity have emerged. The first category is the field in which other alternatives are inconceivable from the techno-economic point of view, e.g., magnets of large thermo-nuclear installations, MHD generators, inductive energy storage systems, etc. The second category comprises areas in which superconductors must compete with existing technologies, e.g., electrical devices, magnetic separators, etc. This paper discusses the development of various low-temperature superconducting devices, estimates their potential and evaluates future applications of HTS, based on the experience accumulated in the USSR and elsewhere. THE POTENTIAL FOR LARGE CRITICAL CURRENTS IN THE HIGH T(SUB c) OXIDES
G. Deutscher *In* Ministry of Energy and Infrastructure, The First Energy Conference: Israel and the Former USSR 15 May 1991 p 150-155 (For primary document see N94-26050 07-44)
Copyright Avail: Issuing Activity (Office of the Chief Scientist, Ministry of Energy and Infrastructure, PO Box 13106, 91130 Jerusalem, Israel)

The potential for high critical current densities is examined. On a thermodynamical basis, the energy scale for vortex pinning can be derived from a measurement of the width of the critical region. This energy scale is on the order of 0.1 eV in YBCO, which is sufficient for practical applications. Another important parameter is the short coherence length. The inner plane length, of the order of a few lattice spacings, is favorable for pinning by point defects. But the very short outer plane length gives rise to anomalous magnetic behavior, unfavorable for high-field applications at high temperature; this is true in particular in the most anisotropic oxides, such as the Bi compounds. ALTERNATIVE MATERIALS FOR SOLID OXIDE FUEL CELLS: PROCESSING AND INTERACTIONS OF MATERIALS
J. L. Bates, T. R. Armstrong, and L. A. Chick 1993 13 p Presented at the Joint Contractors Meeting on Advanced Turbine Systems, Fuel Cells and Coal-Fired Heat, Morgantown, WV, 3-5 Aug. 1993
(Contract DE-AC06-76RL-01830)
(DE94-000016; CONF-930893-35) Avail: CASI HC A03/MF A01

The purpose of this research is to develop alternative materials for solid oxide fuel cell (SOFC) interconnections and electrodes with improved electrical, thermal, and electrochemical properties. The overall approach for this research and development is as follows: minimize the number of cations in the electrode, electrolyte, and interconnection by developing yttrium compounds, such as Y(Ca)CrO3 as the interconnection, and Y(M')MnO3 as the air electrode; develop advanced synthesis and fabrication processes for air sintering, below 1,500 C, of chromite interconnections through: (1) the use of sintering aids, and (2) the synthesis of submicrometer powders; establish methods for the simultaneous processing and consolidation of air-sinterable powders; electrochemically evaluate interface reactions (in reproducible and controlled laboratory tests) for both the alternate and state-of-the-art materials and cell components developed under this program; and evaluate the chemical reactivity and interdiffusion effects that take place between the various fuel cell components--electrolyte/cathode, interconnect/cathode, and interconnect/anode. This paper describes a comprehensive study that assessed the processing of air-sinterable chromites, the sintering mechanism of chromites, and the chemical reactivity and interdiffusional effects between the interconnect, air, and fuel electrodes. Materials evaluated were La(0.7)Ca(0.31)CrO3, La(0.7)Ca(0.29)CrO3, (Y(0.6)Ca(0.4))(1.05)-Cr(0.95)O3, La(1-x)Sr(x)MnO3, La(1-x)Ca(x)MnO3, Y(1-x)Ca(x)MnO3, and Y(1-x)Sr(x)MnO3. DOE

THE STATE OF THE ART OF THIN-FILM PHOTOVOLTAICS
T. Surek Oct. 1993 12 p Presented at the Symposium on Balancing Energy, the Economy, and Ecology: The Solar Energy Contribution, Newark, DE, 16 Feb. 1993
(Contract DE-AC02-83CH-10093)
(DE94-000224; NREL/TP-410-6049; CONF-9302150-1) Avail: CASI HC A03/MF A01

Thin-film photovoltaic technologies, based on materials such as amorphous or polycrystalline silicon, copper indium diselenide, cadmium telluride, and gallium arsenide, offer the potential for significantly reducing the cost of electricity generated by photovoltaics. The significant progress in the technologies, from the laboratory to the marketplace, is reviewed. The common concerns and questions raised about thin films are addressed. Based on the progress to date and the potential of these technologies, along with continuing investments by the private sector to commercialize the technologies, one can conclude that thin-film PV will provide a competitive alternative for large-scale power generation in the future. NEMO 2: NEW ENERGY SYSTEMS AND TECHNOLOGIES
P. Lund (Helsinki Univ. of Technology, Otaniemi, Finland.) 1993 29 p
(DE94-702060; KTM/E-B-132) Avail: CASI HC A03/MF A01

The Advanced Energy Systems and Technologies Research Program (NEMO 2) is one of the main energy research programs of the Ministry of Trade and Industry of Finland for the period of 1993-1998. The main emphasis in NEMO 2 is on solar energy and wind power. These are followed by other small power production, energy storage, and hydrogen technologies. The total budget is about 120 million FIM. The main objective in Nemo 2 is to increase the use of solar and wind energy in Finland and to promote industrial export in this field. Technology research and development is strongly supported and an international leadership role is envisioned for some niche areas. New energy technology is developed as a whole in close cooperation with industry and universities. To enhance the commercialization of these technologies, a small demonstration program is suggested to be realized in connection with the research program. Furthermore, international cooperation is considered important in reaching the program goals. As to wind energy research, basic research on wind meteorology and arctic wind technology will be continued. A series of pilot plants to demonstrate the achievements from wind technology developments is promoted. In solar energy, the NEMO 2 program looks for more efficient and cheaper photovoltaic systems and applications. Manufacturing of new photovoltaic cells is under consideration. Solar heating technologies are also supported with emphasis on improved system demonstrations. Energy storage questions are also dealt with indirectly in connection with solar research and development. DOE

PROGRAMME FOR THE PROMOTION OF WIND POWER PRODUCTION
1993 34 p
(DE94-702065; KTM/E-C-35) Avail: CASI HC A03/MF A01

Promotion of renewable energies has a pretty long history in Finnish energy policy. In its energy policy report to Parliament in the spring of 1992, the Council of State expressed the intention to draw up a long-term program for expanding the wind power capacity in Finland. In the Energy Department of the Finnish Ministry of Trade and Industry, a group of civil servants has been surveying the present status of wind power, the chances for expanding it, and how this energy has been promoted in different countries. The survey is to provide a basis for a first goal-oriented Wind Power Program for Finland. Finland's existing wind power capacity approximates 1.5 MW. The Wind Power Program suggests this to be raised to 100 MW by the year 2005. Even so, less than 0.5% of the estimated electricity requirements would be supplied through wind power. To achieve this modest target, a systematic program would already be necessary. Key actions according to the proposed program would include the continuation of research and development efforts, subsidized construction of installations, different options relating to land use planning, and voluntary agreements between the government and the power producers. Information will also have to be supplied to ensure its implementation. Under the proposed program, the Ministry of Trade and Industry would go on contributing investment aid toward the building of wind power installations. Those to be erected in some early years would be looked upon as 'new technology' ones, which would enable them to be assisted at more than 30% of the total cost if necessary. Installations' improved competitiveness would decrease the aid percentage. DOE

EXPLORATORY TECHNOLOGY RESEARCH PROGRAM FOR ELECTROCHEMICAL ENERGY STORAGE
K. Kinoshita, ed. Oct. 1993 13 p
(Contract DE-AC03-76SF-00098)
(DE94-003480; LBL-34080) Avail: CASI HC A03/MF A01

This summary denotes the progress made by the Exploratory Technology Research (ETR) Program for Electrochemical Energy Storage during calendar year 1992. The primary objective of the ETR program, which is sponsored by the US Department of Energy (DOE) and managed by Lawrence Berkeley Laboratory (LBL), is to identify electrochemical technologies that can satisfy stringent performance, durability, and economic requirements for electric vehicles (EV's). The ultimate goal is to transfer the most promising electrochemical technologies to the private sector or to another DOE program (e.g., SNL's Electric Vehicle Advanced Battery Systems Development Program, EVABS) for further development and scale-up. Besides LBL, which has overall responsibility for the ETR program, LANL and BNL have participated in the ETR program by providing key research support in several of the program elements. Program consists of three major elements: exploratory eesearch; applied science research; and air systems research. The objectives and the specific battery and electrochemical systems addressed by each program element are discussed. Financial information that relates to the various programs and a description of the management activities for the ETR Program are described. DOE

OVERVIEW OF THE PHOTOVOLTAIC MANUFACTURING TECHNOLOGY (PVMaT) PROJECT

C. E. Witt, R. L. Mitchell, and G. D. Mooney Aug. 1993 7 p Presented at the National Conference and Exposition on Heat Transfer, Atlanta, GA, 8-11 Aug. 1993
(Contract DE-AC02-83CH-10093)
(DE93-018234; NREL/TP-411-5361; CONF-930830-31) Avail: CASI HC A02/MF A01

The Photovoltaic Manufacturing Technology (PVMaT) project is a historic government/industry photovoltaic (PV) manufacturing R&D partnership composed of joint efforts between the federal government (through the US Department of Energy) and members of the US PV industry. The project's ultimate goal is to ensure that the US industry retains and extends its world leadership role in the manufacture and commercial development of PV components and systems. PVMaT is designed to do this by helping the US PV industry improve manufacturing processes, accelerate manufacturing cost reductions for PV modules, improve commercial product performance, and lay the groundwork for a substantial scale-up of US-based PV manufacturing capacities. Phase 1 of the project, the problem identification phase, was completed in early 1991. Phase 2, the problem solution phase, which addresses process-specific problems of specific manufacturers, is now underway with an expected duration of 5 years. Phase 3 addresses R&D problems that are relatively common to a number of PV companies or the PV industry as a whole. These 'generic' problem areas are being addressed through a teamed research approach. DOE

LOW-COST PHOTOVOLTAIC INVERTERS INCORPORATING APPLICATION-SPECIFIC INTEGRATED CIRCUITS

George A. OSullivan (Abacus Controls, Inc., Somerville, NJ.) and Joseph A. OSullivan (Washington Univ., Saint Louis, MO.) Oct. 1993 22 p
(Contract DE-AC04-94AL-85000)
(DE94-003270; SAND-93-7076) Avail: CASI HC A03/MF A01

The positive impact of designing a power conditioner control system for photovoltaic applications with an application-specific integrated circuit (ASIC) as the main control element was demonstrated with detailed computer simulations in Phase 1 of a two phase Small Business Innovative Research Grant issued by the US Department of Energy. Completion of the design, building and testing of three prototypes using different power semiconductors was successfully accomplished in Phase 2. The power rating for the residential utility intertied Sunverters Model 753-4-200 is 5 kW. A stand-alone inverter suitable for operation from a photovoltaic array with or without a battery for energy storage was also developed in this effort. A much needed intermediate power level 50-kW three-phase power conditioner, Sunverter Model 759-4-200, was the third product to evolve from the research and development. All designs take advantage of the ASIC and a complementary microprocessor sampled-data control system. The ASIC-controlled power conditioners provide the high reliability, high efficiency, and low cost needed for photovoltaic applications. They cover the power range from the residential level to utility-sized installations. DOE

THE REACTIVITY OF LITHIUM TOWARD NON-AQUEOUS SOLVENTS OF RELEVANCE TO ENERGY STORAGE APPLICATIONS AS STUDIED BY SURFACE ANALYTICAL TECHNIQUES

K. Wang, G. S. Chottiner, and D. A. Scherson Jun. 1993 26 p
(Contract DE-AC03-76SF-00098)
(DE94-003483; LBL-34312) Avail: CASI HC A03/MF A01

The interactions between metallic lithium and perdeuterated tetrahydrofuran (TDF) have been examined in ultrahigh vacuum (UHV) by X-ray photoelectron and Auger electron spectroscopies (XPS and AES, respectively) and temperature programmed desorption (TPD). The AES, XPS, and TPD spectra of thick layers of Li vapor deposited on clean polycrystalline silver (Ag(poly)) foils exposed to up to 100 L TDF at room temperature showed no evidence for features other than those associated with clean Li/Ag(poly) surfaces. This indicates that the sticking coefficient of (gaseous) TDF on Li at 300 K is negligibly small. Clearly defined C(1s) and O(1s) XPS features were observed, however, for submonolayer coverages of TDF on Li/Ag(poly), obtained by first condensing a thick layer of TDF below 140 K and later gently warming the specimen to 300 K. The binding energies of these peaks were smaller than those for condensed TDF at 135 K. The m/e = 48 TPD spectra of TDF condensed on Ag(poly) yielded for O(TDF) less than 1 a well defined peak centered in the range of 210-240 K, a temperature much higher than that associated with the desorption of bulk-like TDF (ca. 170 K). The fragmentation patterns of adsorbed TDF were consistent with cyclopropane and formaldehyde as the most likely thermally desorbed species. Unlike the behavior observed for TDF/Ag(poly) for which no TPD features were detected for T greater than 300 K, the m/e = 4 TPD spectra for TDF/Li/Ag(poly) displayed a prominent peak centered at about 600 K attributed to D2 generated by the thermal decomposition of LiD. This provides rather unambiguous evidence that TDF reacts with Li at temperatures lower than 350 K to yield LiD as the main product. DOE

SOLAR RESOURCE-UTILITY LOAD MATCHING ASSESSMENT: NREL PHOTOVOLTAIC PROJECT SUMMARY

Nov. 1993 4 p
(Contract DE-AC02-83CH-10093)
(DE94-000232; NREL/TP-411-5836) Avail: CASI HC A01/MF A01

Many utility planners may be unfamiliar with the potential for the development of photovoltaics (PV) in their service areas. The goal of the research summarized in this document is to provide information on the match existing between the output of PV powder plants and the load requirements of U.S. utilities. This material indicates whether or not the effective capacity (hence the value) of this renewable resource should be higher than that traditionally assigned to an intermittent resource. DOE

AN OVERVIEW OF DOE'S WIND TURBINE DEVELOPMENT PROGRAMS

A. Laxson, D. Dodge, L. Flowers, R. Loose (Department of Energy, Washington, DC.), and P. Goldman (Department of Energy, Washington, DC.) Sep. 1993 10 p Presented at the 9th Annual Conference and Exhibition of the Canadian Wind Energy Association, Pincher Creek, Canada, 20-22 Sep. 1993
(Contract DE-AC02-83CH-10093)
(DE93-018224; NREL/TP-441-5761; CONF-9309131-1) Avail: CASI HC A02/MF A01

The development of technologically advanced, higher efficiency wind turbines continues to be a high priority activity of the US wind industry. The United States Department of Energy (DOE) is conducting and sponsoring a range of programs aimed at assisting the wind industry with system design, development, and testing. The overall goal is to develop systems that can compete with conventional electric generation for $.05/kWh at 5.8 m/s (13 mph sites) by the mid-1990's and with fossil-fuel-based generators for $.04/kWh at 5.8 m/s sites by the year 2000. These goals will be achieved through several programs. The Value Engineered Turbine Program will promote the rapid development of US capability to manufacture wind turbines with known and well documented records of performance, cost, and reliability, to take advantage of near-term market opportunities. The Advanced Wind Turbine Program will assist US industry to develop and integrate innovative technologies into utility-grade wind turbines for the near-term (mid 1990's) and to develop a new generation of turbines for the year 2000. The collaborative Electric Power Research Institute (EPRI)/DOE Utility Wind Turbine Performance Verification Program will deploy and evaluate commercial-prototype wind turbines in typical utility operating environments, to provide a bridge between development programs currently underway and commercial purchases of utility-grade wind turbines. A number of collaborative efforts also will help develop a range of small systems optimized to work in a diesel hybrid environment to provide electricity for smaller non-grid-connected applications. DOE

DESIGN OF GASIFIERS TO OPTIMIZE FUEL CELL SYSTEMS

Aug. 1993 54 p
(Contract DE-AC21-90MC-27227)
(DE94-000010; DOE/MC-27227/3471) Avail: CASI HC A04/MF A01

Pursuing the key national goal of clean and efficient utilization of the abundant domestic coal resources for power generation, this study was conducted to evaluate the potential of optimizing the integrated catalytic gasification/carbonate fuel cell power generation system. ERC in close collaboration with Fluor Daniel (providing engineering design and costing), conducted a detailed system configuration study to evaluate various catalytic gasification/carbonate fuel cell power plant configurations and compared them to present day, as well as emerging, alternate coal-based power plant technologies to assess their competitive position. A Topical Report was submitted documenting this effort, and the three catalytic gasification case studies are summarized in Appendix A. Results indicate that system efficiencies approaching 55% (HHV) can be achieved by integrating low temperature catalytic gasification with high efficiency carbonate fuel cells. Thermal balance in the gasifier is achieved without oxygen by recycling hydrogen from the fuel cell anode exhaust. A small amount of air is added to the gasifier to minimize hydrogen recycle. In order to validate the assumptions made in the case configurations, experimental studies were performed to determine the reactivity of Illinois No. 6 coal with the gasification catalysts. The reactivity of the catalyzed coal has significant bearing on gasifier sizing and hence system cost and efficiency. DOE

RESEARCH AND DEVELOPMENT OF ALTERNATIVE COMPONENTS AT ARGONNE NATIONAL LABORATORY FOR MOLTEN CARBONATE FUEL CELLS

K. M. Myles, M. Krumpelt, G. H. Kucera, M. Roche, and E. Indacochea 1993 9 p Presented at the Joint Contractors Meeting on Advanced Turbine Systems, Fuel Cells and Coal-Fired Heat, Morgantown, WV, 3-5 Aug. 1993
(Contract W-31-109-eng-38)
(DE94-000014; DOE/NBM-94000014; CONF-930893-29) Avail: CASI HC A02/MF A01

Effort was focused on assessing conductive ceramic oxides as electrode materials and determining effectiveness of alternative electrolyte formulations at reducing NiO solubility, minimizing differential electrolyte migration, and reducing component corrosion. Full-cell tests are being carried out with Co-doped and doubly doped $LiFeO_2$ cathodes and undoped $LiCoO_2$ cathodes. Nb-doped CeO_2 anodes were also tested. Effect of a $CaCO_3$-Li_2CO_3-K_2CO_3 electrolyte on components was studied. DOE

N94-26584# Argonne National Lab., IL.

SEALANT RESEARCH FOR SOLID OXIDE FUEL CELLS

K. M. Myles, I. Bloom, M. Krumpelt, K. L. Ley, S. E. Dorris, and A. S. Wagh 1993 7 p Presented at the Joint Contractors Meeting on Advanced Turbine Systems, Fuel Cells and Coal-Fired Heat, Morgantown, WV, 3-5 Aug. 1993
(Contract W-31-109-eng-38)
(DE94-000015; DOE/NBM-94000015; CONF-930893-28) Avail: CASI HC A02/MF A01

A suitable sealant must form strong, dense bonds with SOFC components, be compatible, be stable at 1000 C in SOFC operating environment (H_2 and H_2O on anode side, O_2 on cathode side), and be electrically insulating. Two types of sealants are being developed: Rigid (Mg ammonium phosphate cement) for the cell edge, and compliant (borate-based glass-ceramic) for stack-to-manifold joining. Testing of both is reported. Shrinkage of the rigid sealant needs to be reduced. Further testing is underway. DOE

MERGING PHOTOVOLTAIC HARDWARE DEVELOPMENT WITH HYBRID APPLICATIONS IN THE USA

W. Bower 1993 8 p Presented at the Solar 1993 Conference, Perth, Australia, 1-5 Dec. 1993
(Contract DE-AC04-94AL-85000)
(DE94-002682; SAND-93-2145C; CONF-931236-1) Avail: CASI HC A02/MF A01

The use of multi-source power systems, 'hybrids,' is one of the fastest growing, potentially significant markets for photovoltaic (PV) system technology today. Cost-effective applications today include remote facility power, remote area power supplies, remote home and village power, and power for dedicated electrical loads such as communications systems. This market sector is anticipated to be one of the most important growth opportunities for PV over the next five years. The U.S. Department of Energy (USDOE) and Sandia National Laboratories (SNL) are currently engaged in an effort to accelerate the adoption of market-driven PV hybrid power systems and to effectively integrate PV with other energy sources. This paper provides details of this development and the ongoing hybrid activities in the United States. Hybrid systems are the primary focus of this paper. DOE

SIMPLIFIED HIGH-EFFICIENCY SILICON CELL PROCESSING

P. A. Basore, J. M. Gee, M. E. Buck, W. K. Schubert, and D. S. Ruby 1993 5 p Presented at the 7th International Photovoltaic Science and Engineering Conference, Nagoya, Japan, 22-26 Nov. 1993
(Contracts DE-AC04-94AL-85000; DE-AC04-76DP-00789)
(DE94-002683; SAND-93-1435C; CONF-931120-1) Avail: CASI HC A01/MF A01

The authors developed an emitter diffusion process that yields a near-ideal doping profile with a passivating oxide in a single furnace step. Because this process subjects the material to only one high-temperature thermal excursion, bulk lifetime is better preserved. This is especially true for lower-cost silicon materials containing a high concentration of oxygen or carbon. Using this process, one-sun cell efficiencies over 19% on float-zone material and over 18% on Czochralski material are routinely obtained. Using solar-grade Czochralski material, record efficiencies of 17.6% at one sun and 20.0% under concentration are demonstrated. Simple processes that yield high-performance diffusion profiles are expected to become increasingly important as manufacturers adopt improved techniques for ohmic contacts. DOE

ANALYSIS/TEST CORRELATION USING VAWT-SDS ON A STEP-RELAXATION TEST FOR THE ROTATING SANDIA 34 m TEST BED

J. G. Argueello, C. R. Dohrmann, T. G. Carne, and P. S. Veers 1993 7 p Presented at the 13th Energy-sources Technology Conference and Exhibition (ETCE) on Wind Energy, New Orleans, LA, 23-26 Jan. 1994
(Contract DE-AC04-76DP-00789)
(DE94-002290; SAND-93-1656C; CONF-940113-3) Avail: CASI HC A02/MF A01

The combined analysis/test effort described compares predictions with measured data from a step-relaxation test in the absence of significant wind-driven aerodynamic loading. The process described is intended to illustrate a method for validation of time domain codes for structural analysis of wind turbine structures. Preliminary analyses were performed to investigate the transient dynamic response that the rotating Sandia 34 m Vertical Axis Wind Turbine (VAWT) would undergo when one of the two blades was excited by step-relaxation. The calculations served two purposes. The first was for pretest planning to evaluate the relative importance of the various forces that would be acting on the structure during the test and to determine if the applied force in the step-relaxation would be sufficient to produce an excitation that was distinguishable from that produced by the aerodynamic loads. The second was to provide predictions that could subsequently be compared to the data from the test. The test was carried out specifically to help in the validation of the time-domain structural dynamics code, VAWT-SDS, which predicts the dynamic response of VAWT's subject to transient events. Post-test comparisons with the data were performed and showed a qualitative agreement between pretest predictions and measured response. However, they also showed that there was significantly more damping in the measurements than included in the predictions. Efforts to resolve this difference, including post-test analyses, were undertaken and are reported. The overall effort described represents a major step in the process of arriving at a validated structural dynamics code. DOE

MSOFC DEVELOPMENT STATUS
R. A. Gibson and N. Q. Minh 1993 7 p Presented at the Joint Contractors Meeting on Advanced Turbine Systems, Fuel Cells and Coal-Fired Heat, Morgantown, WV, 3-5 Aug. 1993
(Contract DE-AC21-89MC-26006)
(DE94-003192; DOE/MC-26006/94/C0252; CONF-930893-38) Avail: CASI HC A02/MF A01

The objective is to develop materials and fabrication methodologies to develop a monolithic solid oxide fuel cell (MSOFC) system capable of meeting performance, life, and cost goals for coal-derived fuel applications. The program is aimed at fabrication and testing of a 100-W stack. The MSOFC is an all-ceramic structure in which the cell components are configured in a compact, corrugated array; the electrolyte is zirconia, the anode is Ni/Y2O3-ZrO2 cermet, the cathode is doped LaMnO3, and the interconnects are doped LaCrO3. The fabrication sequence is shown, along with electrochemical performance. Baseline anode formulation shrinks when exposed to hydrogen causing cell curvature and stack delamination; new anode compositions are being developed. Sealants are being developed at Argonne. Thermal expansion mismatches need to be taken into account. DOE

THE PLVCR 500 AND HCPC, TESTS AND RESULTS
Volker Leuchsner Sep. 1991 44 p
(ISSN 0939-298X)
(DLR-Mitt-93-04; ETN-94-95206) Avail: CASI HC A03/MF A01

Developments of volumetric receivers during the last decade which have pointed out the advantages and the wide range of applications in comparison with tube receivers are reported. During three test periods in 1990 the 500 kW version of the Pressure Loaded Volumetric Ceramic Receiver (PLVCR 500) and the Hexagonal Compound Parabolic Concentrator (HCPC) were mounted on the Small Solar Power System (SSPS) tower. Concerning the size of the experiment, it represents the most extensive research and development work on pressure loaded volumetric receivers until now. The receiver and the secondary concentrator were tested together and separately. A gauge pressure of 4.2 bars at air outlet temperatures of 960 C was reached. The secondary concentrator was tested under various flux conditions, the inlet and outlet flux distributions were measured. With this test the feasibility of a modular design of receiver and secondary concentrator could be shown. ESA

FEASIBILITY STUDY ON INTRODUCTION OF THE BIO-FUEL POWER GENERATION IN TROPICAL REGIONS
Mar. 1993 168 p In JAPANESE Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-725203; NEDO-P-9214) Avail: CASI HC A08

Study is made on feasibility of introducing the bio-fuel power generation in tropical regions, especially in South East Asia including Okinawa and South America. Biomass promising as bio-fuel is bagasse and palm oil mill dregs; and bagasse is found to be advantageous to the use for large-scaled power generation. Prospective uses of bagasse are a combined use of gasification process and gas turbine power generation, an effective use of gas turbine exhaust heat at sugar cane factories, and a use of the system to be developed which totalizes these two. As to how to carry out the R and D project, since the gasification power generation process itself is a high technology and has partially unknown fields, it is desirable that research and development are conducted in such technologically developed countries as Japan (Okinawa). A developmental plan, therefore, is worked out as such that a pilot plant of approximately 3000kW is to be constructed in Okinawa because the period for bagasse production is at least 3 months there, and a commercial-scale plant is to be constructed and operated in such big bagasse-producing countries as Brazil. DOE

HANDBOOK OF PHOTOVOLTAIC POWER GENERATING DESIGN FOR INTRODUCTION
Mar. 1993 49 p
(DE94-725199; ETDE/JP-mf-94725199) Avail: CASI HC A03/MF A01

The purpose of this handbook is to survey the ways to introduce photovoltaic power generation with specifying a certain region of introduction by international cooperation. Various cases of load requirements and load patterns are taken up for more efficient designing of equipment. When actually introducing photovoltaic power generating facilities, more detailed analyses of the situation would be necessary, but this handbook is effective in investigating and comparing basic designs and possible regions of introduction. Presented are illustrated overall designing procedures of photovoltaic power generating facilities and examples in cases of DC load and AC load. This handbook includes assumed load formats, calculation of storage battery capacity, required capacity of photovoltaic cell, selection of photovoltaic cell module, selection of storage battery, selection of inverter, selection of charge controller, list of possible regions, and amounts and durations of insolation in the selected regions, as data for designing photovoltaic power generation for introduction. DOE

EXTRACTION OF MODAL PARAMETERS FROM AN OPERATING HAWT USING THE NATURAL EXCITATION TECHNIQUE (NExT)
G. H. James 1993 17 p Presented at the 13th Energy-Sources Technology Conference and Exhibition (ETCE) on Wind Energy, New Orleans, LA, 23-26 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-001831; SAND-93-2271C; CONF-940113-1) Avail: CASI HC A03/MF A01

The Natural Excitation Technique (NExT) is used to extract modal parameters (natural frequencies, modal damping, and mode shapes) from an operating Horizontal Axis Wind Turbine (HAWT). NExT uses the measured response from the turbine excited by the assumed broad-band, random wind input even though the excitation cannot be directly measured. The damping, measured using NExT, generally increased in the system as the wind speed increased. Such information can be used to aid in the verification and upgrade of codes which predict structural response of operating HAWT's and aid our understanding of the dynamics of wind turbines. The Northern Power Systems 100-kW machine is addressed. Strain data is available from this machine while operating at 72 rpm in 10, 15, 20, 25, and 30 mph winds. The operational modal frequencies and mode shapes were measured for this machine. Reconstructions of the auto and cross spectra are used to verify the validity of the extracted parameters. The modal damping for two modes are presented for this range of wind speeds.

PEROVSKITE SOLID ELECTROLYTES FOR SOFC
A. F. Sammells 1993 7 p Presented at the Joint Contractors Meeting on Advanced Turbine Systems, Fuel Cells and Coal-Fired Heat, Morgantown, WV, 3-5 Aug. 1993
(Contract DE-FG02-90ER-80910)
(DE94-001923; DOE/ER-80910/94/C0267; CONF-930893-5) Avail: CASI HC A02/MF A01

A new series of brownmillerite solid electrolyte phases Ba2GdIn(1-x)Ga(x)O(5) (x = 0,0.2,0.4) with the x = 0.2 phase exhibiting an unusually low E were synthesized. Relative to both the observed ionic conductivity in this phase and to E(sub a)s observed in similar compounds. We attribute measured ionic conductivities to a lack of available charge carriers in Ba2GdIn(0.8)Ga(0.2)O(5). However, the low E(sub a) supports the premise that brownmillerite solid electrolyte structures are suitable for supporting high ionic conductivity. Current work is focusing on enhancing the amount of charge carriers in these materials by systematically introducing disorder into the brownmillerite lattice. DOE

SOLAR COLLECTOR MANUFACTURING ACTIVITY, 1992
Nov. 1993 70 p
(DE94-003401; DOE/EIA-0174(92)) Avail: CASI HC A04/MF A01

This report presents data provided by US-based manufacturers and importers of solar collectors. Summary data on solar thermal collector shipments are presented for the years 1974 through 1992. Summary data on photovoltaic cell and module shipments are presented for the years 1982 through 1992. Detailed information for solar thermal collectors and photovoltaic cells and modules are presented for 1992. Appendix A describes the survey methodology. Appendix B contains the 1992 survey forms and instructions. Appendices C and D list the companies that responded to the 1992 surveys and granted permission for their names and addresses to appear in the report. Appendix E provides selected tables from this report with data shown in the International System of Units (SI) metric units. Appendix F provides an estimate of installed capacity and energy production from solar collectors for 1992. DOE

Various researches on the production of liquid fuels from biomass were undertaken. Carbon monoxide and/or hydrogen were used in most cases, while processes using a little or none of these reducing gas were investigated. The following results on thermochemical conversion of wood biomass are presented, in which wood is reacted in aqueous solution in the presence of an alkali catalyst without reducing gases, which yielded a liquid product: (1) the optimum reaction condition is determined from systematic studies carried out with reaction parameter and variety of catalyst; (2) the optimum organic solvents are determined from investigations concerning production of heavy oil which is easily separable from an aqueous layer; (3) the effectiveness of the repeated use of reaction solvent is indicated by experiments in which water or a 2-propanol/water mixture is used repeatedly as a reaction solvent; and (4) heavy oil obtained by the liquefaction process was analyzed by (1) H-NMR (Nuclear Magnetic Resonance), GC (Gas Chromatography) - MS (Mass Spectrometry), and acid-base extraction. The liquefaction technology may be evaluated as one of the highly promising biomass conversion technologies, although some technical problems, such as separation or upgrading of heavy oils need to be solved. For the promotion of a total system, in which biomass is planted and grown and then the biomass is used as fuel and/or chemicals, further development of technologies are needed not only for conversion itself but also for plantation, afforestation, and irrigation. A supported continuous fiber emitter comprised of ytterbia fibers is evaluated for a gas-fired thermophotovoltaic energy conversion application. Optical recuperation as an efficiency enhancer is considered. Photo-convertible radiation efficiency and ytterbia volatility establish the operating temperature of the fibrous emitter. Gas-fired emitters exhibiting a high luminous output are proposed. NTIS

CONTINUOUS ROLL-TO-ROLL a-Si PHOTOVOLTAIC MANUFACTURING TECHNOLOGY
M. Izu Dec. 1993 84 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE94-000260; NREL/TP-411-6003) Avail: CASI HC A05/MF A01

This report describes work done under a 3-year program to advance ECD's roll-to-roll, triple-junction photovoltaic manufacturing technologies, to reduce the module production costs, to increase the stabilized module performance, and to expand commercial capacity utilizing ECD technology. The specific 3-year goal is to develop advanced large-scale manufacturing technology incorporating ECD's earlier research advances with the capability of producing modules with stable 11% efficiency at a cost of approximately $1.00 per peak watt. Accomplishments during Phase 1 included: (1) ECD successfully incorporated a high-performance Ag/metal-oxide back-reflector system into its continuous roll-to-roll commercial production operation. (2) High-quality a-Si-Ge narrow-band-gap solar cells were incorporated into the manufacturing. (3) ECD demonstrated the continuous roll-to-roll production of high-efficiency, triple-junction, two-band-gap solar cells consistently and uniformly throughout a 762-m (2500-ft) run with high yield. (4) ECD achieved 11.1% initial sub-cell efficiency of triple-junction, two-band-gap a-Si alloy solar cells in the production line. (5) The world's first 0.37-sq m (4-sq ft) PV modules were produced utilizing triple-junction spectrum-splitting solar cells manufactured in the production line. (6) As a result of process optimization to reduce the layer thickness and to improve the gas utilization, ECD achieved a 77% material cost reduction for germane and 58% reduction for disilane. Additionally, ECD developed a new low-cost module that saves approximately 30% in assembly material costs. DOE

HIGH-EFFICIENCY, THIN-FILM SOLAR CELLS
Ronald P. Gale Jan. 1994 40 p Prepared in cooperation with Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE94-000250; NREL/TP-451-5746) Avail: CASI HC A03/MF A01

This report describes work on a 3-year research program to investigate thin-film GaAs/GaInP cells using the cleavage of lateral epitaxial film for transfer (CLEFT) technique, and to determine the process to enable overgrowth of GaAs films using organometallic chemistry. Application of the CLEFT thin-film technique to GaInP/GaAs solar cells and organometallic overgrowth was investigated. A problem of alloy contamination was identified and controlled, leading to higher quality layers. Solar cell structures were grown and fabricated using previously determined growth parameters for GaAs and GaInP. With the improved materials developed significant improvements were made in solar cell performance. Conditions for in-situ overgrowth by organometallic chemical vapor deposition (OMCVD) were determined and continuous GaAs layers were grown over a separation mask layer. The layers were successfully separated from their substrate using the CLEFT process, demonstrating the application of overgrowth using OM chemistry with HCl. DOE

THE 1993 NASA AEROSPACE BATTERY WORKSHOP
Jeffrey C. Brewer, comp. Washington Feb. 1994 817 p Workshop held in Huntsville, AL, 16-18 Nov. 1993
(NASA-CP-3254; M-739; NAS 1.55:3254) Avail: CASI HC A99/MF A10

This document contains the proceedings of the 26th annual NASA Aerospace Battery Workshop, hosted by the Marshall Space Flight Center on 16-18 Nov. 1993. The workshop was attended by scientists and engineers from various agencies of the U.S. Government, aerospace contractors, and battery manufacturers, as well as international participation in like kind from a number of countries around the world. The subjects covered included nickel-cadmium, nickel-hydrogen, nickel-metal hydride, and lithium based technologies, as well as advanced technologies including various bipolar designs. For individual titles, see N94-28101 through N94-28136.

A summary of NASA Aerospace Flight Battery Systems Program Activities is presented. The NASA Aerospace Flight Battery Systems Program represents a unified NASA wide effort with the overall objective of providing NASA with the policy and posture which will increase the safety, performance, and reliability of space power systems. The specific objectives of the program are to: enhance cell/battery safety and reliability; maintain current battery technology; increase fundamental understanding of primary and secondary cells; provide a means to bring forth advanced technology for flight use; assist flight programs in minimizing battery technology related flight risks; and ensure that safe, reliable batteries are available for NASA's future missions. NSWC CRANE AEROSPACE CELL TEST HISTORY DATABASE
Harry Brown and Bruce Moore *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 83-89 (For primary document see N94-28100 07-44)
Avail: CASI HC A02/MF A10

The Aerospace Cell Test History Database was developed to provide project engineers and scientists ready access to the data obtained from testing of aerospace cell designs at Naval Surface Warfare Center, Crane Division. The database is intended for use by all aerospace engineers and scientists involved in the design of power systems for satellites. Specifically, the database will provide a tool for project engineers to review the progress of their test at Crane and to have ready access to data for evaluation. Additionally, the database will provide a history of test results that designers can draw upon to answer questions about cell performance under certain test conditions and aid in selection of a cell for a satellite battery. Viewgraphs are included. Derived from text

A test program was conducted to characterize five space-quality nickel-hydrogen (NiH2) battery cells. A subset of those tests was also done on five commercial nickel-cadmium (NiCd) cells, for correlation to the characteristics of an Energy Storage Unit Simulator. The test program implemented the recommendations of a 1991 study, as reported to IECEC-92. The findings of the tests are summarized, and expected impacts on the performance of the electrical power system (EPS) of a large space-based radar (SBR) surveillance satellite are derived. The main characteristics examined and compared were terminal voltage (average and transient) and capacity through discharge, equivalent series resistance, derived inductance and capacitance, charge return efficiency, and inter-pulse charge effectiveness. A new procedure is described which was recently developed to quantify loading uniformity of nickel and cadmium plates and to screen finished electrodes prior to cell assembly. The technique utilizes the initial solubility rates of the active material in a standard chemical deloading solution at fixed conditions. The method can provide a reproducible indication of plate loading uniformity in situations where high surface loading limits the free flow of deloading solution into the internal porosity of the sinter plate. A preliminary study indicates that 'good' cell performance is associated with higher deloading rates. Author

ANALYSIS FOR NICKEL (3 AND 4) IN POSITIVE PLATES FROM NICKEL-CADMIUM CELLS
Harlan L. Lewis *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 141-146 (For primary document see N94-28100 07-44)
Avail: CASI HC A02/MF A10

The NASA-Goddard procedure for destructive physical analysis (DPA) of nickel-cadmium cells contains a method for analysis of residual charged nickel as NiOOH in the positive plates at complete cell discharge, also known as nickel precharge. In the method, the Ni(III) is treated with an excess of an Fe(II) reducing agent and then back titrated with permanganate. The Ni(III) content is the difference between Fe(II) equivalents and permanganate equivalents. Problems have arisen in analysis at NAVSURFWARCENDIV, Crane because for many types of cells, particularly AA-size and some 'space-qualified' cells, zero or negative Ni(III) contents are recorded for which the manufacturer claims 3-5 percent precharge. Our approach to this problem was to reexamine the procedure for the source of error, and correct it or develop an alternative method.

SPACE STATION FREEDOM NIH2 CELL TESTING PROGRAM
Bruce Moore (Naval Surface Warfare Center, Crane, IN.) and Dave Frate *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 149-239 (For primary document see N94-28100 07-44)
Avail: CASI HC A05/MF A10

Testing for the Space Station Freedom Nickel Hydrogen Cell Test Program began in 1990 at Crave Division, Naval Surface Warfare Center. The program has included receipt inspection, random vibration, acceptance, characterization, and life cycle testing of Ni-H2 cells in accordance with the NASA LeRC Interagency Order C-31001-J. A total of 400 Ni-H2 cells have been received at NAVSURFWARCENDIV Crane from three separate manufacturers; Yardney Technical Products (Yardney), Eagle Picher Industries (Eagle Picher), and Gates Energy Products (Gates). Of those, 308 cells distributed among 39 packs have undergone life cycle testing under a test regime simulating low earth orbit conditions. As of 30 September 1993, there are 252 cells assembled into 32 packs still on life cycle test. Since the beginning of the program, failed cells have been detected in all phases of testing. The failures include the following; seven 65 AmpHr and 81 AmpHr Yardney cells were found to be leaking KOH on receipt, one 65 AmpHr Eagle Picher cell failed the acceptance test, one 65 AmpHr Gates cell failed during the characterization test, and six 65 AmpHr Gates cells failed the random vibration test. Of the 39 life cycle packs, testing on seven packs, 56 cells, has been suspended because of low end of discharge voltages. All of the failed life cycle packs were cycled at 60% depth of discharge.

SAFT NICKEL HYDROGEN CELL CYCLING STATUS
Yannick Borthomieu and Didier Duquesne *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 261-288 (For primary document see N94-28100 07-44)
Avail: CASI HC A03/MF A10

An overview of the NiH2 cell development is given. The NiH2 SAFT system is an electrochemical (single or dual) stack (IPV). The stack is mounted in an hydroformed Inconel 718 vessel operating at high pressure, equipped with 'rabbit ears' ceramic brazed electrical feedthroughs. The cell design is described: positive electrode, negative electrode, and stack configuration. Overviews of low earth orbit and geostationary earth orbit cyclings are provided. DPA results are also provided. The cycling and DPA results demonstrate that SAFT NiH2 is characterized by high reliability and very stable performances.

CALCULATION OF THE THERMONEUTRAL POTENTIAL OF NICd AND NIH2 CELLS
Albert H. Zimmerman *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 289-293 (For primary document see N94-28100 07-44)
Avail: CASI HC A01/MF A10

The thermoneutral potential of a nickel cadmium or nickel hydrogen cell is the potential at which the cell charge or discharge process puts out zero heat, and thus is the potential corresponding to the enthalpy change of the charge/discharge reaction, delta H. A relatively straightforward method for obtaining the thermoneutral potential E(sub tn), is based on the measured potential and temperature derivative of the cell reactions, which are related to the free energy change delta G, and entropy change delta S, respectively. Particularly in the nickel hydrogen cell, the pressure of hydrogen can often vary over an order of magnitude or more during the course of a charge or discharge. In a nickel cadmium cell, although significant changes in oxygen pressure can occur during charge or discharge, since oxygen does not enter into the charge/discharge reaction, these pressure changes are related to the heat generated from oxygen evolution and recombination. However, the entropy changes due to changes in hydrogen pressure relative to the 1 atm standard state must be included to apply this method to the nickel hydrogen cell.

PERFORMANCE MODEL OF A RECIRCULATING STACK NICKEL HYDROGEN CELL
Albert H. Zimmerman *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 295-327 (For primary document see N94-28100 07-44)
Avail: CASI HC A03/MF A10

A theoretical model of the nickel hydrogen battery cell has been utilized to describe the chemical and physical changes during charge and overcharge in a recirculating stack nickel hydrogen cell. In particular, the movement of gas and electrolyte have been examined as a function of the amount of electrolyte put into the cell stack during cell activation, and as a function of flooding in regions of the gas screen in this cell design. Additionally, a two-dimensional variation on this model has been utilized to describe the effects of non-uniform loading in the nickel-electrode on the movement of gas and electrolyte within the recirculating stack nickel hydrogen cell. The type of nonuniform loading that has been examined here is that associated with higher than average loading near the surface of the sintered nickel electrode, a condition present to some degree in many nickel electrodes made by electrochemical impregnation methods. The effects of high surface loading were examined primarily under conditions of overcharge, since the movement of gas and electrolyte in the overcharging condition was typically where the greatest effects of non-uniform loading were found. The results indicate that significant changes in the capillary forces between cell components occur as the percentage of free volume in the stack filled by electrolyte becomes very high. These changes create large gradients in gas-filled space and oxygen concentrations near the boundary between the separator and the hydrogen electrode when the electrolyte fill is much greater than about 95 percent of the stack free volume. At lower electrolyte fill levels, these gaseous and electrolyte gradients become less extreme, and shift through the separator towards the nickel electrode. Similarly, flooding of areas in the gas screen cause higher concentrations of oxygen gas to approach the platinum/hydrogen electrode that is opposite the back side of the nickel electrode. These results illustrate the need for appropriate pore size distributions, and the maintenance of both convective electrolyte and gas flow paths through the stack, if the recirculating stack nickel hydrogen cell design is to work properly.

CHARGE EFFICIENCY OF NI/H2 CELLS DURING TRANSFER ORBIT OF TELSTAR 4 SATELLITES
W. C. Fang, Dean W. Maurer, B. Vyas, and M. N. Thomas *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 405-422 (For primary document see N94-28100 07-44)
Avail: CASI HC A03/MF A10

The TELSTAR 4 communication satellites being manufactured by Martin Marietta Astro Space (Astro Space) for AT&T are three axis stabilized spacecraft scheduled to be launched on expendable vehicles such as the Atlas or Ariane rockets. Typically, these spacecraft consist of a box that holds the electronics and supports the antenna reflectors and the solar array wings. The wings and reflectors are folded against the sides of the box during launch and the spacecraft is spun for attitude control in that phase; they are then deployed after achieving the final orbit. The launch phase and transfer orbits required to achieve the final geosynchronous orbit typically take 4 to 5 days during which time the power required for command, telemetry, attitude control, heaters, etc., is provided by two 50 AH nickel hydrogen batteries augmented by the exposed outboard solar panels. In the past, this situation has presented no problem since there was a considerable excess of power available from the array. In the case of large high powered spacecraft such as TELSTAR 4, however, the design power levels in transfer orbit approach the time-averaged power available from the exposed surface area of the solar arrays, resulting in a very tight power margin. To compound the difficulty, the array output of the spinning spacecraft in transfer orbit is shaped like a full wave rectified sine function and provides very low charging rates to the batteries during portions of the rotation. In view of the typically low charging efficiency of alkaline nickel batteries at low rates, it was decided to measure the efficiency during a simulation of the TELSTAR 4 conditions at the expected power levels and temperatures on three nickel hydrogen cells of similar design. The unique feature of nickel hydrogen cells that makes the continuous measurement of efficiency possible is that hydrogen is one of the active materials and thus, cell pressure is a direct measure of the state of charge or available capacity. The pressure is measured with a calibrated strain gage mounted on the outside of the pressurized cell. Author

ORBITAL MANAGEMENT AND DESIGN CONSIDERATIONS FOR NiCd SATELLITE POWER SYSTEMS
Benjamin J. Tausch, II *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 425-437 (For primary document see N94-28100 07-44)
Avail: CASI HC A03/MF A10

Several recently manufactured 50 and 60 ampere hour aerospace NiCd battery cell lots, produced by Gates Aerospace Batteries, are prone to premature on orbit performance degradation. The failure mechanism is cadmium migration, and the consequent development of soft shorts. A Martin Marietta Astronautics satellite program instituted an orbital management strategy for a set of these batteries that reduced the rate of degradation and brought the system to stable operation. This strategy involves: (1) minimizing the accumulated battery overcharge; (2) regular discharge exercises; and (3) periodic battery reconditioning. Because of changes in the NiCd cell manufacturing process, the actual performance of subsequent lots of NiCd cells is open to question. Future NiCd based power system designs should therefore allow for fine control of charge parameters, and an on orbit battery reconditioning capability. To minimize risk, it is much better to perform a full life test to qualify the cells before launch, rather than in parallel with orbital operations. If there are any changes in the manufacturing process of cells, it is extremely important to maintain very strong cognizance of secondary subcontractors, recognizing that the cell and battery manufacturing discipline is easily atrophied. The Upper Atmosphere Research Satellite (UARS), designed, built, integrated, tested, and operated by NASA and Martin Marietta is a low-Earth orbiting, Earth-observing spacecraft which was launched via Space Shuttle

Discovery on September 12, 1991 and deployed three days later. The Modular Power Subsystem (MPS) onboard the satellite is equipped with three NASA Standard 50 Ampere-hour (Ah) nickel-cadmium (NiCd) batteries. McDonnell Douglas Electronics Systems Company fabricated the MPS, and batteries from Gates Aerospace Batteries cells. Nominal battery performance was achieved for the first four months of spacecraft operation. First evidence of anomalous battery performance was observed in January 1992, after the first maximum beta angle (low Depth of Discharge) period. Since then, the Flight Operations Team (FOT), under the direction of Goddard Space Flight Center's UARS Project and Space Power Application Branch, has monitored and managed battery performance by adjusting solar array offset angle, conducting periodic deep discharge, and controlling battery recharge ratio. This paper covers a brief overview of the UARS, the FOT's operational battery management, and the observed spacecraft battery performance. Author

DISCRIMINATING PERFORMANCE PARAMETERS FOR 50 AMP-HOUR AND 60 AMP-HOUR NICKEL-CADMIUM PLATES AND BATTERY CELLS
Mark R. Toft *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 545-576 (For primary document see N94-28100 07-44)
Avail: CASI HC A03/MF A10

This is a follow-up of studies of the NASA standard 50 AH cell presented at the NASA battery workshop each of the last two years. This is a dynamic study. Data trends continue to be developed and analyzed for their utility in judging NiCd performance. The trends and parameters presented here may bear relevance to many designs of conventional NiCd batteries, not just the 50 AH and 60 AH sizes. Author (revised)

BATTERY CHARGE CONTROL: WHICH APPROACH IS BEST?
Charles Lurie *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 585-588 (For primary document see N94-28100 07-44)
Avail: CASI HC A01/MF A10

The question of the best approach for battery charge control is addressed from two points of view: from the battery point-of-view; and from the spacecraft/mission point-of-view. In terms of performance, more aggressive charging can result in higher discharge voltage and capacity; however, aggressive charging usually implies more overcharge at higher rates and a concomitant higher end of charge temperature (higher stress, shorter life). In terms of life, benign charging can result in lower discharge voltage and capacity (poorer performance). Additionally, benign, or low stress charging, usually implies less overcharge at lower rates with lower end of charge temperature (lower stress, longer life). A discussion of these topics is presented in viewgraph form. Author (revised)

Tests to establish current-voltage characteristics at selected temperatures for 9 a-h Super Nickel-Cadmium cells were conducted at Hughes Industrial Electronics Company's Electron Dynamics Division (HIEC/EDD) under sponsorship of NASA/GSFC through their prime spacecraft contractors Fairchild Space (SMEX/SAMPEX) and TRW (TOMSEP). Curves were constructed using techniques established by Webster, Ford, et al, at NASA/GSFC in the late 1960's - early 1970's time period for conventional nickel cadmium cells used on OAO and OSO aircraft. The NASA/GSFC techniques were slightly modified by HIEC/EDD to fit the Super Ni-Cd situation. Author (revised)

ADVANCED NICKEL-HYDROGEN SPACECRAFT BATTERY DEVELOPMENT
Dwaine K. Coates, Chris L. Fox, D. J. Standlee, and B. K. Grindstaff *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 643-651 (For primary document see N94-28100 07-44)
Avail: CASI HC A02/MF A10

Eagle-Picher currently has several advanced nickel-hydrogen (NiH2) cell component and battery designs under development including common pressure vessel (CPV), single pressure vessel (SPV), and dependent pressure vessel (DPV) designs. A CPV NiH2 battery, utilizing low-cost 64 mm (2.5 in.) cell diameter technology, has been designed and built for multiple smallsat programs, including the TUBSAT B spacecraft which is currently scheduled (24 Nov. 93) for launch aboard a Russian Proton rocket. An advanced 90 mm (3.5 in.) NiH2 cell design is currently being manufactured for the Space Station Freedom program. Prototype 254 mm (10 in.) diameter SPV batteries are currently under construction and initial boilerplate testing has shown excellent results. NiH2 cycle life testing is being continued at Eagle-Picher and IPV cells have currently completed more than 89,000 accelerated LEO cycles at 15% DOD, 49,000 real-time LEO cycles at 30 percent DOD, 37,800 cycles under a real-time LEO profile, 30 eclipse seasons in accelerated GEO, and 6 eclipse seasons in real-time GEO testing at 75 percent DOD maximum. Nickel-metal hydride battery development is continuing for both aerospace and electric vehicle applications. Eagle-Picher has also developed an extensive range of battery evaluation, test, and analysis (BETA) measurement and control equipment and software, based on Hewlett-Packard computerized data acquisition/control hardware. DEVELOPMENT OF NICKEL-METAL HYDRIDE CELL: AN UPDATE

S. Kuwajima, Hiroaki Kusawake, Kensuke Nakatani (Sanyo Electric Co. Ltd., Sumoto, Japan.), and Y. Yano (Sanyo Electric Co. Ltd., Sumoto, Japan.) *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 653-685 (For primary document see N94-28100 07-44)

Avail: CASI HC A03/MF A10

This paper presents in viewgraph format an overview of NASDA's evaluation of commercial nickel metal-hydride (Ni-MH) cells and the development and testing of Ni-MH cells for use in space. The commercial cells are concluded to be feasible and suitable for use in LEO; for GEO, the durability for overcharge is needed because long-term charge retention is required. For the aerospace Ni-MH cell design, two activation procedures are applied to evaluate the effect of the difference in the amount of overcharge protection and precharge. Specific energy of the Ni-MH cell is nearly accomplished at 50 Wh/kg. Initial characteristics indicate the effect derived from precharge. Thirty-five amp-hour class Ni-MH cells have good performance for LEO cycle of 25 and 40 percent DOD up to 3000 cycles as similar to commercial cells. The effect of the difference in the amount of overcharge protection will appear in life test. CASI

NI-MH STORAGE TEST AND CYCLE LIFE TEST

R. Dan Dell, Glenn C. Klein, and David F. Schmidt *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 687-700 (For primary document see N94-28100 07-44)

Avail: CASI HC A03/MF A10

Gates Aerospace Batteries is conducting two long term test programs to fully characterize the NiMH cell technology for aerospace applications. The first program analyzes the effects of long term storage upon cell performance. The second program analyzes cycle life testing and preliminary production lot testing. This paper summarizes these approaches to testing the NiMH couple and culminates with initial storage and testing recommendations. Long term storage presents challenges to deter the adverse condition of capacity fade in NiMH cells. Elevated but stabilized pressures and elevated but stabilized end-of-charge voltages also appear to be a characteristic phenomenon of long term storage modes. However, the performance degradation is dependent upon specific characteristics of the metal-hydride alloy. To date, there is no objective evidence with which to recommend the proper method for storage and handling of NiMH cells upon shipment. This is particularly critical due to limited data points that indicate open circuit storage at room temperature for 60 to 90 days will result in irrecoverable capacity loss. Accordingly a test plan was developed to determine what method of mid-term to long-term storage will prevent irrecoverable capacity loss. The explicit assumption is that trickle charging at some rate above the self-discharge rate will prevent the irreversible chemical changes to the negative electrode that result in the irrecoverable capacity loss. Another premise is that lower storage temperatures, typically 0 C for aerospace customers, will impede any negative chemical reactions. Three different trickle charge rates are expected to yield a fairly flat response with respect to recoverable capacity versus baseline cells in two different modes of open circuit. Specific attributes monitored include: end-of-charge voltage, end-of-charge pressure, mid-point discharge voltage, capacity, and end-of-discharge pressure. Cycle life testing and preliminary production lot testing continue to dominate the overall technology development effort at GAB. The cell life test program reflects continuing improvements in baseline cell designs. Performance improvements include lower and more stable charge voltages and pressures. The continuing review of production lot testing assures conformance to the design criteria and expectations. This is especially critical during this period of transferring technology from research and development status to production. Author (revised)

DETERMINATION OF THERMAL PROPERTIES OF COMMERCIAL NI-MH CELLS

Eric C. Darcy *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 701-716 (For primary document see N94-28100 07-44)

Avail: CASI HC A03/MF A10

The test objectives were to evaluate the electrical and thermal performance of commercial Ni-MH cells, evaluate the effectiveness of commercial charge control circuits, assess the abuse tolerance of these cells, and correlate performance and abuse tolerances to cell design via disassembly. Design objectives were to determine which cell designs are most suitable for scale-up and to guide the design of future shuttle and space station based battery chargers. Results, displayed in viewgraph format, include: reflex charging with ICS circuit resulted in premature charge termination; Ni-MH cells appear very tolerant to overcharge at low rates; Enstore's charger is more electrically and thermally efficient at high rates; and Ni-MH cycles much more efficiently than Ni-Cd with the delta-V/delta-t termination. BIPOLAR Ag-Zn BATTERY

L. John Giltner *In* NASA. Marshall Space Flight Center, The 1993 NASA Aerospace Battery Workshop Feb. 1994 p 773-774 (For primary document see N94-28100 07-44)

Avail: CASI HC A01/MF A10

The silver-zinc (AgZn) battery system has been unique in its ability to safely satisfy high power demand applications with low mass and volume.

However, a new generation of defense, aerospace, and commercial applications will impose even higher power demands. These new power demands can be satisfied by the development of a bipolar battery design. In this configuration the power consuming, interelectrode current conductors are eliminated while the current is then conducted via the large cross-section electrode substrate. Negative and positive active materials are applied to opposite sides of a solid silver foil substrate. In addition to reducing the weight and volume required for a specified power level, the output voltage performance is also improved as follows. Reduced weight through: elimination of the plastic cell container; elimination of plate leads and intercell connector; and elimination of internal plate current collector. Increased voltage through: elimination of resistance of current collector; elimination of resistance of plate lead; and elimination of resistance of intercell connector. EPI worked previously on development of a secondary bipolar silver zinc battery. This development demonstrated the electrical capability of the system and manufacturing techniques. One difficulty with this development was mechanical problems with the seals. However, recent improvements in plastics and adhesives should eliminate the major problem of maintaining a seal around the periphery of the bipolar module. The seal problem is not as significant for a primary battery application or for a requirement for only a few discharge cycles. A second difficulty encountered was with activation (introducing electrolyte into the cell) and with venting gas from the cell without loss of electrolyte. During previous work, the following projections for energy density were made from test data for a high power system which demonstrated in excess of 50 discharge/charge cycles. Projected system power = 100 kilowatts; discharge time = 30 seconds; discharge current density = 1.75 amps/sq in.; system weight = 86 lbs (9.7 WH/lb); and system volume = 1071 cu. in. (.78 WH/cu. in.). EPI is currently working on a development program to produce a bipolar silver-zinc battery design for NASA. The potential application would be to power electromechanical actuators for space launch vehicles. Derived from text

AIR POLLUTION TRANSPORT MODELING M.S. Thesis
David M. Paal Dec. 1993 123 p
(AD-A273863; AFIT/ENC/GCS/93D-1) Avail: CASI HC A06/MF A02

This research effort addresses modeling of the transportation of air pollution in the atmosphere and the numerical analysis of the partial differential equations used in such modeling. Three Gaussian models are examined and compared using example problems. Several finite difference schemes are developed to solve the partial differential equations used in air pollution transport modeling. Three Gaussian models: SCREEN, AFTOX, and the program GAUSPLUM are studied. The model GAUSPLUM is developed and uses the Ada programming language and the analytic solution to the advection-diffusion equation. Numerical analysis of the partial differential equations (PDE) used in air pollution modeling is also examined. The equations are generally parabolic or hyperbolic PDE's. The following are examined in this research: the advection equation; the one-, two-, and three-dimensional advection-diffusion equations; and the two-dimensional steady-state equation. DTIC

ANALYSIS AND DEVELOPMENT OF AN F-5 POLLUTION PREVENTION MANAGEMENT PROGRAM WITH RECOMMENDATIONS FOR CREATION OF SIMILAR PROGRAMS FOR OTHER AIRCRAFT M.S. Thesis
Janice M. Gavern Sep. 1993 154 p
(AD-A274016; AFIT/GLM/LSY/93S-19) Avail: CASI HC A08/MF A02

A pollution prevention program for the F-5 aircraft was developed, and its utility and applicability as a generic framework for similar programs is described. A representative set of F-5 technical orders was analyzed by hand, and the identified chemicals, materials, and processes were loaded into a spreadsheet data base for additional analysis. The Environmental Protection Agency EPA 17 chemical list, and lists of ozone depleting chemicals (ODC's) were used as criteria to identify, for minimization, reduction, or elimination from use on the F-5, a hazardous material (hazmat) subset of those chemicals and materials which had already been identified. The identified hazmat substances were then 'rolled-up' into an F-5 Pollution Prevention Management Plan. Program management use and implementation of the information set out in such a plan were also described. Recommendations for additional research and development, and for required tools were included. Finally, actual examples of all of the material created were attached to the document. DTIC

The contamination of the soil with hazardous chemicals which affect people's health is investigated. The contamination may be direct, by diffusion, or indirect, by polluting the ground water and the water supply. Knowledge concerning the propagation of these chemicals is of great importance. The following situation is considered: water, where chemicals are dissolved, is injected into the soil; the injection of water induces a flow field; the chemicals undergo various reactions with the soil particles; and the adsorption reaction is assumed very fast in comparison to the ground water flow. Concentration equations are given, and the concentration profile near the well is obtained. ESA

SENSITIVITY OF CLIMATE MODELS: COMPARISON OF SIMULATED AND OBSERVED PATTERNS FOR PAST CLIMATES
J. Kutzbach, R. J. Oglesby, W. L. Prell, and T. Webb, III Aug. 1993 17 p
(Contract DE-FG02-85ER-60304)
(DE93-019934; DOE/ER-60304/9) Avail: CASI HC A03/MF A01

Predicting the potential climatic effects of increased concentrations of atmospheric carbon dioxide requires the continuing development of climate models. Confidence in the predictions will be much enhanced once the models are thoroughly tested in terms of their ability to simulate climates that differ significantly from today's climate. During the past several years, the authors have used paleoclimatic data to test the accuracy of the NCAR CCM0 (National Center for Atmospheric Research, Community Climate Model, Version 0), after changing its boundary conditions to those appropriate for past climates. Research has shown that comparing the model results with the data is an evolutionary process, because the models, the data, and the methods for comparison are continually being improved. From 1991 to 1993 the authors have completed new modeling experiments, further analyzed previous model experiments, updated existing sets of paleoclimatic data, made new comparisons between data and model results, and participated in workshops on paleoclimatic modeling. Analyses of air trapped in polar ice cores, in conjunction with recent atmospheric measurements, indicate that the atmospheric methane concentration increased by about 250% during the past two or three hundred years. Because methane is a potent 'greenhouse' gas, the increasing concentrations are expected to contribute to global warming. The timing of the methane increase suggests that it is related to the rapid growth of the human population and associated industrialization and agricultural development. The specific causes of the atmospheric methane concentration increase are not well known, but may relate to either increases in methane sources, decreases in the strengths of the sinks, or both. DOE

EVALUATION OF A CANADIAN MINITUBE AIR SAMPLING SYSTEM [UTVAERDERING AV KANADENSISK UTRUSTNING FOER PROVTAGNING OCH ANALYS AV ORGANISKA LUFTFOERORENINGAR]
Lars Rittfeldt Feb. 1993 25 p In SWAHILI
(ISSN 0347-2124)
(FOA-C-40307-4.6; ETN-94-95283) Avail: CASI HC A03/MF A01

The evaluation of a 'Minitube air sampling system' is described. The system is designed for automatic low level measurements of organic substances in air. It makes use of cassettes with fifty 'Tenax Minitubes' for the sampling and analysis. The performance of the system was tested and evaluated. The results indicate that most volatile organic substances can easily be analyzed down to the ppb level. At lower concentrations measures must be taken to eliminate the contamination of the Tenax tubes that occurs due to passive sampling (the tubes have open ends and are not completely sealed). ESA

GRASSLAND/ATMOSPHERE RESPONSE TO CHANGING CLIMATE: COUPLING REGIONAL AND LOCAL SCALES
M. B. Coughenour, T. G. F. Kittel, R. A. Pielke, and J. Eastman Oct. 1993 63 p
(Contract DE-FG02-90ER-60932)
(DE94-003111; DOE/ER-60932/3) Avail: CASI HC A04/MF A01

The objectives of the study were: to evaluate the response of grassland ecosystems to atmospheric change at regional and site scales, and to develop multiscaled modeling systems to relate ecological and atmospheric models with different spatial and temporal resolutions. A menu-driven shell was developed to facilitate use of models at different temporal scales and to facilitate exchange information between models at different temporal scales. A detailed ecosystem model predicted that C3 temperate grasslands wig respond more strongly to elevated CO2 than temperate C4 grasslands in the short-term while a large positive N-PP response was predicted for a C4 Kenyan grassland. Long-term climate change scenarios produced either decreases or increases in Colorado plant productivity (NPP) depending on rainfall, but uniform increases in N-PP were predicted in Kenya. Elevated CO2 is likely to have little effect on ecosystem carbon storage in Colorado while it will increase carbon storage in Kenya. A synoptic climate classification processor (SCP) was developed to evaluate results of GCM climate sensitivity experiments. Roughly 80% agreement was achieved with manual classifications. Comparison of 1x and 2xCO2 GCM Simulations revealed relatively small differences. DOE

ENVIRONMENTAL BENEFITS OF DIFFERENT TYPES OF HEAT PUMPS, AVAILABLE AND EXPECTED
P. J. Hughes 1993 29 p Presented at the 2nd International Conference on Heat Pumps in Cold Climates, Moncton, New Brunswick, 16-17 Aug. 1993
(Contract DE-AC05-84OR-21400)
(DE94-002440; CONF-9308189-1) Avail: CASI HC A03/MF A01

A brief overview of integrated resource planning (IRP) is provided, with emphasis on how stakeholders interact within the process and where the opportunities may lie for heat pump advocates in cold climates. Five heat pump options that represent various approaches for improving heat pump cold weather performance are included here in a comparative analysis: 2-speed electric air source heat pumps, variable-speed electric air source heat pumps, electric ground-source heat pumps, natural gas engine-driven heat pumps, and natural gas absorption heat pumps. The comparative analysis addresses seasonal performance, seasonal peak demand, air pollutant emissions, customer energy costs, and recognition of environmental externalities in IRP, all in the context of a residential application in the Great Lakes region of the U.S. Several actions that may be in the interest of heat pump stakeholders in cold climates were identified: development of improved software for utility planners, advocacy of a practical form of the Societal Test for use in IRP that credits heat pumps for the residential air pollutant emissions that they avoid, and development of practical methods to credit heat pumps with other environmental benefits for which they may be responsible. The World Climate Data and Monitoring Program continued its help in improving climate data management. The World Climate Applications and Services Program has developed an inventory of climate application related activities in WMO member countries. Other developments have been the encouragement of national climate program development and projects related to mitigation of drought. The World Climate Research Program is organized through seven main projects: Climate model development; Research on climate processes; Global Energy and Water Cycle Experiments (GEWEX); Tropical Ocean and Global Atmosphere (TOGA); World Ocean Circulation Experiment (WOCE); Study of global change; Scientific exploration of satellite data, in particular in the areas of clouds and the hydrological cycle, transport of greenhouse gases and their distribution in the atmosphere, global ocean circulation and transport of heat and chemicals, polar climate and sea ice, surface hydrological processes and their relation to vegetation. The World Climate Impact Studies Program (WCIP) in 1990/91 was structured to give to: (1) Greenhouse Gases/Climate Change; (2) Coordination of Climate Impact Activities; (3) Methods of Climate Impact Assessment; and (4) Monitoring of erosion, flooding, desertification and high urban atmospheric pollution. A class of explicit finite difference advection schemes derived along the method of lines is examined. An important problem field is large scale atmospheric transport, and therefore focus is on the demand of positivity and on the use of locally refined grids. For the spatial discretization, attention is confined to directionally split schemes in conservation form using five points per direction. The fourth order central scheme and the family of k-schemes comprising the second order central, the second order upwind, and the third order upwind biased discretization are studied. Positivity is enforced through flux limiting. The limited third order upwind discretization is concluded to be the best candidate from the four examined. For the time integration, attention is confined to a number of explicit Runge-Kutta methods of orders two up to four. With regard to the demand of positivity, these integration methods turn out to behave almost equally and no best method could be identified. For solutions with steep gradients, a local uniform grid refinement technique is proposed as an effective tool to speed up computations. ESA

SIHTI 2: ENERGY AND ENVIRONMENTAL TECHNOLOGY
K. Saviharju and A. Johansson 1993 47 p
(DE94-702061; KTM/E-B-134) Avail: CASI HC A03/MF A01

The program is divided into system and technology parts. The aim of system studies is to determine, on the basis of life cycle analyses, long-term environmental / technological aims for various fields (energy, industry) and to find out an optimum strategy for reaching these aims. The analysis will give data on emission reduction costs and on fields where technical improvements are required, and will determine the limits set by environmental factors for future technical development. Environmental impacts will be discussed from national and economic viewpoints. Technological development is dependent on new ideas. The aim is to indicate possibilities for reducing emissions from energy use of peat and wood, for low-emission production at least in one industrial field (wood-processing industry), to establish emission measuring and control methods, to indicate utilization alternatives for solid matter separated at power plants, and to find out operable alternatives for the energy use of wastes. Other ventures of significance will also be financed: survey of 'new' emissions and development of their measuring and purification methods. The field of the program will be divided into synergic sub-fields: systematics of emission chains, fields of operation (energy and environment problems in the wood-processing industries), development of flue gas purification technology, measuring and control technology, by-products of power plants, emissions from peat production, etc. DOE

A CONCEPTUAL FRAMEWORK FOR THE EVALUATION OF COST-EFFECTIVENESS OF PROJECTS TO REDUCE GHG EMISSIONS AND SEQUESTER CARBON
J. Sathaye, R. Norgaard, and W. Makundi Jul. 1993 29 p
(Contract DE-AC03-76SF-00098)
(DE93-040448; LBL-33859) Avail: CASI HC A03/MF A01

This paper proposes a conceptual framework for evaluating the cost of projects to reduce atmospheric greenhouse gases (GHG's). The evaluation of cost-effectiveness should account for both the timing of carbon emissions and the damage caused by the atmospheric stock of carbon. We develop a conceptual basis to estimate the cost-effectiveness of projects in terms of the cost of reducing atmospheric carbon (CRAC) and other GHG's. CRAC accounts for the economic discount rate, alternative functional forms of the shadow price, the residence period of carbon in the atmosphere, and the multiple monetary benefits of projects. The last item is of particular importance to the developing countries. DOE

AN OBSERVATIONAL STUDY OF AIR POLLUTION TRANSPORT OVER A LARGE URBAN COMPLEX [DAITOSHIIKI JOKU NI OKERU OSEN BUSSHITSU YUSO NO KANSOKUTEKI KENKUY]
Hiroshi Yoshikado, Tateki Mizuno, Hiroaki Kondo, Koji Kitabayashi, Shigeo Shimogata, and Susumu Yamamoto 28 May 1993 139 p In JAPANESE
(ISSN 0926-9989)
(Rept-6; ETN-94-80513) Avail: CASI HC A07/MF A02

A series of intensive wide range observations of local meteorology and air pollution was carried out during six years from 1986 to 1991 in the western portion of the Kanto Plain, including the Tokyo metropolitan area. The following two important meteorological structures closely related with the air pollution in large urban areas were clarified: (1) local wind system characteristics in summer; and (2) air stagnation frequently occurring in early winter. The following subjects are discussed: (1) the significance of the present research from the historical point of view and in the current field of research of air pollution forecasting and assessment; (2) introduction of data obtained and the general description of weather conditions during each observation periods of 1986 through 1991; (3) analysis of the vertical structure of the sea breeze which penetrates inland from Tokyo Bay; and (4) analysis of the meteorological conditions which are concerned with the very high level of pollutants frequently occurring in early winter in the Tokyo area. A THREE-DIMENSIONAL CHEMICAL TRANSPORT MODEL STUDY OF THE 1991 ANTARCTIC OZONE HOLE USING OBJECTIVELY ANALYSED DATA M.S. Thesis
John Wade Sandilands Jul. 1993 179 p
(ISBN-0-315-84250-4; CTN-94-61030) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The development of the ozone hole over the Antarctic was investigated using a three dimensional spectral chemical transport model at R-15 resolution for the period of September 15 to October 15, 1991. The model is driven by objectively analyzed wind fields and uses the chemical module developed by Kaminski (1993), which contains simplified stratospheric chemistry. A rudimentary temperature flag is also included to initiate the heterogeneous reactions essential to large ozone reductions during the austral spring. Initial chemical conditions are based on the two-dimensional fields of Garcia and Solomon (1983). Four model experiments that involve varying the temperature flags for the heterogeneous chemistry and altering some of the model's dynamical and chemical code all show that, although extensive processing of NO(y) and Cl(x) occurs within the model, the ozone hole that develops appears shallow and ephemeral. Analysis of components of the equation governing the model's evolution indicates that meridional ozone transport suffices to overwhelm the substantial chemical depletion that does occur. It is concluded that the objectively analyzed data improperly represent the dynamical conditions of the southern polar region and are unable to capture the essential isolated nature of the vortex. A ROBUST UPWIND DISCRETIZATION METHOD FOR ADVECTION, DIFFUSION AND SOURCE TERMS

Barry Koren Apr. 1993 24 p Submitted for publication
(ISSN 0169-0388)
(CWI-NM-R9308; ETN-94-9512) Avail: CASI HC A03/MF A01

A finite volume discretrization for advection diffusion equations with source term is described and applied. The complete space discretization is second to third order accurate and monotone. Good accuracy and monotonicity are guaranteed by an appropriate limiter function in the upwind advection operator. The discretization of diffusion is standard, second order central. For source terms, an evaluation is proposed which is consistent with that of the advection terms. It leads to improved accuracy, as well as to improved residual convergence for steady problems. The complete space discretization works well for both smooth and non smooth problems. This good robustness is considered to be the method's main property. Except for two novelties (the limiter function and the source term evaluation), the space discretization is standard and well proven in for example aircraft aerodynamics computations. In air pollution transport computations it is not. It is thought that it can be successfully applied in the latter field as well. ESA

MEASURING VARIATION IN ECOSYSTEM SENSITIVITY TO STRESS Annual Technical Report, Oct. 1992 - Nov. 1993

John Cairns, Jr., Paul V. McCormick, Matthew E. Arnegard, and Eric P. Smith 29 Nov. 1993 84 p
(Grant AF-AFOSR-0379-91)
(AD-A274232; AFOSR-93-0905TR) Avail: CASI HC A05/MF A01

This report presents the results of field studies which were designed to investigate the variability in periphyton sensitivity to stress. Chlorine and sulfuric acid were experimentally delivered to periphyton communities using chemical-diffusing substrates. Significant variations in chlorine sensitivity among ecosystems were generally not explained by differences in water quality characteristics, but may be related to differences in the inherent tolerance of algal taxa to chlorine exposure. Periphyton community biomass and oxygen consumption did not respond to decreases in pH as low as pH=3; taxonomic responses to this manipulation are still being analyzed. The report also describes a study of stress induced tolerance of periphyton communities to novel copper stress using chemical diffusers. DTIC

NUMERICAL ANALYSIS OF THE PHOTO-DISSOCIATION/RADICAL OXIDATION OF FORMALDEHYDE BY ULTRAVIOLET LIGHT IN A PHOTOLYTIC REACTOR M.S. Thesis

Robert O. Fetter Dec. 1993 73 p
(AD-A274539) Avail: CASI HC A04/MF A01

The release of volatile organic compounds (VOC's) into the atmosphere has come under fire by the Environmental Protection Agency (EPA) and state regulatory agencies in the past several years. These releases come from a wide variety of sources from gasoline filling stations to industrial and military operations. A new pollution control technology currently under development utilizes ultraviolet (UV) light to break down the volatile organic compounds (VOC's) contained in an airstream. One pollution control equipment manufacturer has already employed this method in an installation in California. DTIC

LEADEX ENVIRONMENTAL PHENOMENA AND EFFECTS OBSERVED BY DMSP, NOAA, AND ERS-1 SATELLITES Final Report, 25 Mar. - 24 Apr. 1992

Robert W. Fett Nov. 1993 106 p
(Contract N00014-92-C-6018)
(AD-A274596; NRL/PU/7530-93-0008) Avail: CASI HC A06/MF A02

This report examines notable atmospheric and cryospheric conditions observed by satellites over the Beaufort Sea region surrounding the Leadex ice camp position. DMSP and NOAA direct readout high resolution data include visible and infrared scenes in a variety of discrete channels. The special sensor microwave imager (SSM/I) data of DMSP and the synthetic aperture radar (SAR) data of the European ERS-1 satellite are of special interest and value in evaluating changes in ice appearance and configuration noted during the period of Leadex from 25 March to 24 April 1992. Multi-channel comparisons of the various data types over the same location and correlation with available ground truth data yield significant insights into the nature and state of the phenomena observed. FEASIBILITY STUDY ON CONSTRUCTION OF A GLOBAL ENVIRONMENT RESEARCH AND DEVELOPMENT INFORMATION NETWORK

Mar. 1993 193 p In ENGLISH and JAPANESE
(DE94-725198; ETDE/JP-mf-94725198) Avail: CASI HC A09/MF A03

Investigations are made for effective connection of a greenhouse gas technology information exchange system (Green-TIE) plan with a technology transfer scheme by the Asia Pacific Economic Cooperation Organization. Information in the energy/environmental field has not been used very effectively, or the personnel network has not yet been formed in the local area. Technology information on the Green-TIE plan has already been demonstrated and is greatly needed in developing countries in terms of liability, cost, and access method. In providing policy information as the other value-added service, it is mainly administrative organizations that provide policy information on technology already demonstrated. As to support of technology information exchange which is original to developing countries, construction of the developing country information source database is supported by cooperation with administrative organization. Direct technology transfer support is realized by heightening adjusting function of the joint project in liaison with each country. It is necessary for Japan to cooperate in promotion and arrangement of the system so as to make these international technology information networks useful. DOE

ADVANCES IN PASSIVE-REMOTE AND EXTRACTIVE FOURIER TRANSFORM INFRARED SPECTROSCOPIC SYSTEMS

J. C. Demirgian, C. Hammer, E. Hwang, and Zhuo-Xiong Mao 1993 11 p Presented at the Air and Waste Management Association's (AWMA) International Specialty Conference, Atlanta, GA, 11-14 Oct. 1993
(Contract W-31-109-eng-38)
(DE94-001424; ANL/CMT-ACL/CP-80970; CONF-9310197-1) Avail: CASI HC A03/MF A01

The Clean Air Act of 1990 requires the monitoring of air toxics including those from incinerator emissions. Continuous emission monitors (CEM) would demonstrate the safety of incinerators and address public concern about emissions of hazardous organic compounds. Fourier transform infrared (FTIR) spectroscopy can provide the technology for continuous emission monitoring of stacks. Stack effluent can be extracted and analyzed in less than one minute with conventional FTIR spectrometers. Passive-remote FTIR spectrometers can detect certain emission gases over 1 km away from a stack. The authors discuss advances in both extractive and passive-remote FTIR technology. Extractive systems are being tested with EPA protocols, which will soon replace periodic testing methods. Standard operating procedures for extractive systems are being developed and tested. Passive-remote FTIR spectrometers have the advantage of not requiring an extracted sample; however, they have less sensitivity. We have evaluated the ability of commercially available systems to detect fugitive plumes and to monitor carbon monoxide at a coal-fired power plant. DOE

MACROBENTHIC FAUNA IN THE DUTCH SECTOR OF THE NORTH SEA IN 1991

G. C. A. Duineveld 1992 23 p
(PB94-126414; NIOZ-1992-6) Avail: CASI HC A03/MF A01

The present report describes and discusses the results of a macrobenthic survey made in spring 1991 in the Dutch Sector of the North Sea. The survey is meant to be a part of a long term biological monitoring program of the benthic fauna in the area, an initiative of the Tidal Water Division of Rijkswaterstaat (RWS). The common interest of the participants is to obtain an insight into the year-to-year variations of the macrobenthos and in the factors governing these fluctuations. The stations for the present survey were selected from current as well as previous benthic research programs in the area. One set of stations was provided by the Tidal Water Division. At these particular stations, ongoing measurements on water and sediment quality are being conducted in the framework of a chemical monitoring program, and, moreover, some of the stations were sampled for macrofauna on earlier occasions. INITIAL ULTRAVIOLET-B INTENSITY DATA AT LAWRENCE LIVERMORE NATIONAL LABORATORY
Kenneth O. Patten, Jr., Donald J. Wuebbles, and Gerald J. Smith (New Zealand Inst. for Industrial Research and Development, Lower Hutt.) Oct. 1993 25 p
(Contract W-7405-eng-48)
(DE94-004279; UCRL-ID-115334) Avail: CASI HC A03/MF A01

A measurement of UV-B reaching the ground has been established at the Lawrence Livermore National Laboratory. The instrument is the same as those operated by the National Institute for Water and Atmospheric Research in their network in New Zealand. The wavelength response of the radiometer is similar to the response of human skin to UV-B. Intensity data are collected by averaging meter readings over 10 minutes from 6:00 am to 6:00 pm Pacific Standard Time, then converting to effective UV-B intensity normalized at 310 nm. This report checks the intensities obtained at LLNL from November 1992 to July 1993 against the expected results: increased solar zenith angle, whether from the daily cycle or from the yearly cycle in solar position, should decrease UV-B intensity at the ground due to increased optical path; and intervening cloud cover should decrease ground UV-B intensity. Three additional findings are reported here: maximum UV-B intensity on cloudless days does not always follow a smooth curve, but instead varies either high or low to some extent; morning UV-B intensities are less than those in the afternoon at comparable solar zenith angles at certain times of year; LLNL wintertime daily-averaged UV-B intensities are somewhat higher than those observed at Auckland, New Zealand in their winter of 1992. ASCOT (Atmospheric Studies in Complex Terrain) is a multi-laboratory U.S. Department of Energy research program studying the properties of atmospheric boundary layers over non-uniform terrain and the interactions among various scales of motion that influence those properties. Within this context, one of the principal goals of the ASCOT program is to provide information necessary for an accurate description of transport and diffusion processes for atmosphere pollutants that may be released in regions of complex terrain. Three examples from past ASCOT research relevant to this goal are presented. Current and proposed research in the Front Range region of Colorado in the vicinity of the Rocky Flats Plant is also described. DOE

COASTAL ZONE MANAGEMENT ACT AND RELATED LEGISLATION, REVISION 3
15 Oct. 1993 135 p
(Contract DE-AC05-84OR-21400)
(DE94-004180; ORNL/M-3027-Rev-3) Avail: CASI HC A07/MF A02

In recognition of the increasing pressures upon the nation's coastal resources, Congress enacted the Coastal Zone Management Act in 1972. Its purpose is to encourage states to preserve, protect, develop, and, where possible, restore or enhance such valuable natural resources as wetlands, floodplains, estuaries, beaches, dunes, barrier islands, and coral reefs, as well as the fish and wildlife utilizing those habitats. A unique feature of the act is that participation by states is voluntary. One key provision for encouraging states to participate is the availability of federal financial assistance to any coastal state or territory, including those on the Great Lakes, which is willing to develop and implement a comprehensive coastal management program. Additionally, the Coastal Barrier Resources Act (CBRA) was passed in 1983. This report contains the legislative history and statutes associated with each act. Regulations for implementation and other guidance are included. DOE

Avail: CASI HC A02/MF A02

Various chemical substances have come to be detected in ambient water, following recent industrial activities and diversification of life style. Since quite a few of those substances are harmful to health, measures to assure the safety of water, such as drinking water, have been considered among various countries of which the industrialized countries take a leading part, and the new standards and the guiding principles were presented. With such international movements for a background, amendment of laws concerning preservation of the quality of ambient water and measures for such quality control are going to be practiced also in Japan. To begin with, water quality standards were drastically revised after 34 years, and they will be enforced in December 1993. Environmental standards have been reviewed as well, reflecting the changes in water quality standards, for the purpose of quality assurance of water for public use, which is, the fundamental source of waterworks. A total of 15 new items such as organic chlorides and pesticides have been added to be regulated in the environmental standards. Requisites for lead and arsenic became more strict. 'Audit items' were established for water quality maintenance. In addition to these revisions and amendments, a new environmental standard will be set on a basis of quantitative relations between nitrogen/phosphorus concentration and water quality index. COLLABORATION OF CHEMICAL OXIDATION AND BIOLOGICAL TREATMENT FOR REMOVAL OF REFRACTORY ORGANIC SUBSTANCES [NAN BUNKAISEI YUGAI YUKI KAGAKU BUSSHITSU NO KAGAKU SANKA TO SEIBUTSU SHORI NO HEIYO NI YORU SHORI]

Hiroyasu Ichikawa, Shinji Wada, and Kenji Tatsumi *In its* Journal of NIRE, Volume 2, Number 4 26 Jul. 1993 p 11-2 In JAPANESE (For primary document see N94-28147 07-45)

Avail: CASI HC A02/MF A02

Various refractory organic substances such as aromatic chloro and nitro compounds are present at significant concentrations in wastewater from organic chemical industries. These chemicals are hardly removed by the activated sludge method and are discharged into the environment where they remain since they are hard to decompose by microorganisms and inhibit microorganism activity. The accumulation of these chemicals in the environment pollutes and destroys the ecosystem. To remove refractory substances in wastewater from the chemical industry, it is necessary to establish a chemical oxidation and biological treatment to be used in combination. For this purpose, the oxidative decomposition of refractory chemicals and biodegradability of the reaction products were studied. This report gives an outline of the treatment of refractory organic substances with combined use of chemical oxidation and biological treatment. Author (NASDA)

EFFECTS OF p-CHLOROPHENOL ON SULFATE REDUCTION IN MARINE SEDIMENTS [ENGAN KAIYO TAISEKIBUTSUCHU NO RYUSAN KANGEN KASSEI NI OYOBOSU PARAKUROROFENORU NO EIKYO]

Manabu Fukui, Junln Suh (Shimane Univ., Matsue, Japan.), Yoshitaka Yonezawa, and Yoshikuni Urushigawa *In its* Journal of NIRE, Volume 2, Number 4 26 Jul. 1993 p 21-2 In JAPANESE (For primary document see N94-28147 07-45)

Avail: CASI HC A02/MF A02

The effects of p-chlorophenol (concentration; zero, 10, 100, 500, and 1,000 micro-M) on bacterial sulfate reduction were examined in three coastal sediments of Ise Bay, Japan. Sulfate reduction rate (13 nmol per ml day) at A3 point (34 deg 59 min 00 sec N, 136 deg 44 min 05 sec E, water depth, 20.5 m) was similar to that at E3 point (34 deg 51 min 55 sec N, 136 deg 44 min 20 sec E, water depth, 36 m) and higher than that at B1 point (34 deg 56 min 50 sec N, 136 deg 40 min 30 sec E, water depth, 16 m). At A3 point, sulfate reduction rates were stimulated by p-chlorophenol up to 100 micro-M, but inhibited at 500 and 1,000 micro-M. At E3 point, p-chlorophenol did not affect sulfate reduction rates up to 500 micro-M and inhibited slightly the activity at 1,000 micro-M. p-Chlorophenol stimulated sulfate reduction at B1 point up to 1,000 micro-M. Sulfate-reducing bacteria would, thus, appear to utilize low concentrations of p-chlorophenol as a substrate in coastal sediment. Author (NASDA)

TREATMENT OF REFRACTORY ORGANIC SUBSTANCES WITH COMBINED USE OF CHEMICAL OXIDATION AND BIOLOGICAL TREATMENT. PART 2: BIODEGRADABILITY OF OZONATION PRODUCTS OF CHLOROPHENOL [KAGAKU SANKA TO SEIBUTSU SHORI NO HEIYO NI YORU NANBUNKAISEI YUKI KAGAKU BUSSHITSU NO SHORI. DAI 2 HO: KUROROFENORU NO OZON SANKABUTSU NO SEIBUNKAISEI]

Hiroyasu Ichikawa, Shinji Wada, and Kenji Tatsumi *In its* Journal of NIRE, Volume 2, Number 4 26 Jul. 1993 p 29-3 In JAPANESE (For primary document see N94-28147 07-45)

Avail: CASI HC A02/MF A02

To remove refractory substances in wastewater from the chemical industry, it is necessary to establish a chemical oxidation and biological treatment to be used in combination. For this purpose, the oxidative decomposition of refractory chemicals and biodegradability of the reaction products were studied. The solution of p-chlorophenol and 2,4-dichlorophenol were ozonated in the ozone concentration range, 24.2 to 26.5 mg/l. Chlorophenols were rapidly reduced and after 45 - 60 minutes ozonation could no longer be detected. However, Dissolved Organic Carbon (DOC) was only reduced to about 50 percent even after 120 minutes ozonation. Ozonation of chlorophenols led to the formation of oxalic and formic acids as major products and small amounts of acetic acid. A mixture of the ozonated solution with non-acclimated sludge culture was incubated for four days at 25 C, and the biodegradability was evaluated using DOC reduction. DOC of chlorophenols was hardly reduced even after a four-day incubation, indicating little biodegradability. For the ozonation solution of p-chlorophenol in which most of them was decomposed, DOC removal of more than 80 percent was attained and DOC in the solution was less than 10 ppm. Author (NASDA)

DETERMINATION OF LEAD ISOTOPE RATIOS IN SEAWATER BY PURGE AND TRAP GC/MS AFTER ETHYLATION [PAJI ANDO TORAPPU GC/MS NI YORU BIRYO NAMARI NO DOITAIHI BUNSEKI]

Takashi Imagawa, Hiroaki Tao, and Akira Miyazaki *In its* Journal of NIRE, Volume 2, Number 4 26 Jul. 1993 p 37-4 In JAPANESE (For primary document see N94-28147 07-45)

Avail: CASI HC A02/MF A02

A 1-ml portion of sodium tetraethylborate was added to sample water and heated from room temperature to 100 C to convert inorganic lead to tetraethyllead. Tetraethyllead was purged by helium for 18 min at a flow rate of 15 ml/min and trapped on fused silica tube cooled at -10 C. The tube was heated rapidly to 220 C and the tetraethyllead was introduced to ion source of GC (Gas Chromatography)/MS (Mass Spectroscopy). Ion intensities of Pb(C2H5)3(+) were measured at m/z from 291 to 295. The effects of fragment ions and C-13 containing ions were corrected by calculation to obtain the isotopic ratios of Pb-204, 206, 207 and 208. The isotopic ratio of NIST (National Institute of Standards and Technology) SRM (Standard Reference Materials) 81 and 82, measured by the present method agreed with the certified value within one percent. By this method, it was possible to determine the isotopic ratio of lead in a seawater sample whose concentration was 0.1 ppb. The effect of the blank and other causes of systematic errors should be removed to obtain more accurate results required in the case of discussing the differences in environmental samples. Author (NASDA)

ENVIRONMENTAL MANAGEMENT AND AUDIT [KANKYO KANRI - KANSA NI TSUITE]

Tateki Mizuno *In its* Journal of NIRE, Volume 2, Number 4 26 Jul. 1993 p 45-5 In JAPANESE (For primary document see N94-28147 07-45)

Avail: CASI HC A02/MF A02

Environmental audit which started in the late 80's has recently been introduced to Japan. Although Japan has been a leading country in environmental pollution prevention, its environmental management has been just a risk management dealing with only a part of the whole issue, not covering global environmental problems. In Europe and the United States, where the controls of governments are not so strong, environmental management does not penetrate private companies very much. Under these circumstances, European countries started introducing environmental audit to companies, and Japan is expected to keep pace with them. ISO (International Standarization Organization) and IEC (International Electrotechnical Commission) have been considering international standardization of environmental management and audit, and established a devoted technical committee. Such ISO standards may be incorporated with JIS (Japanese Industrial Standards) in Japan. IEC proposes to conduct both internal audit (audit by a third party within a company) and external audit (audit by a third party outside a company), whereas ICC (International Chamber of Commerce) as well as ILO (International Labor Organization), UNEP (United Nations Environment Program), WHO (World Health Organization), and OECD (Organization for Economic Cooperation and Development) propose only internal audits. OIL PRODUCTION FROM BUCKWHEAT STILLAGE BY THERMOCHEMICAL LIQUEFACTION [NETSU KAGAKU HANNO NI YORU SOBAJOCHU ZANSA KARA NO OIRU NO SEIZO]

Tomoaki Minowa, Yutaka Dote, Tomoko Ogi, and Shinya Yokoyama *In its* Journal of NIRE, Volume 2, Number 4 26 Jul. 1993 p 53-6 In JAPANESE (For primary document see N94-28147 07-45)

Avail: CASI HC A02/MF A02

Stillage from the ethanol fermentation of buckwheat was converted directly into oil by thermochemical liquefaction for the recovery of energy in the form of liquid fuel. The stillage with moisture content of 83 weight percent was heated under pressurized nitrogen at reaction temperature of 200 - 325 C and holding time of zero to 60 min with or without sodium carbonate as catalyst. Oil yield decreased by catalyst addition and increased with increasing reaction temperature. The oil yield obtained at holding time of 30 min had the highest value among the yield at zero to 60 min. The oil was obtained in the maximum yield of 58 percent on an organic basis at reaction temperature of 325 C, operating pressure of 15 MPa and holding time of 30 min without catalyst. This oil had a calorific value of 38.1 MJ/kg, viscosity of 320 mPa sec., carbon content of 74.1 percent, hydrogen content of 10.3 percent, oxygen content of .9 percent, and nitrogen content of 5.8 percent. These values satisfy the specification of No. 3-2 fuel oil in JIS (Japanese Industrial Standards). Buckwheat stillage is an ideal raw material of liquefaction in terms of oil yield and its properties, compared to sweet potato stillage, barley stillage, and rice stillage. The high crude fat content and low crude fiber content of buckwheat stillage may possibly be the reasons for its high oil yield. Author (NASDA)

EFFECTS OF SLOT ON ROCK SURFACE FOR PERCUSSIVE ROCK EXCAVATION: WATER JET ASSISTED PERCUSSIVE ROCK EXCAVATION Report No. 1 [DAGEKI KUSSAKU NI OYOBOSU SESSAKUKO NO EIKYO: SUI FUNRYU HEIYO DAGEKI KUSSAKU GIJUTSU NI KANSURU KENKYU]

Keiji Hanada, Norio Yamakado (Japan Foundation Engineering Co. Ltd., Osaka.), Hirohide Hayamizu (Japan Foundation Engineering Co. Ltd., Osaka.), Masanobu Sanai (Japan Foundation Engineering Co. Ltd., Osaka.), and Masato Utsumi (Japan Foundation Engineering Co. Ltd., Osaka.) *In its* Journal of NIRE, Volume 2, Number 4 26 Jul. 1993 p 63-7 In JAPANESE (For primary document see N94-28147 07-45)

Avail: CASI HC A03/MF A02

To evaluate the effects of slot cut on rock surface for water jet assisted percussive rock excavation, a laboratory investigation was performed. The main results are summarized as follows: (1) slot cut on the rock surface is very effective for water jet assisted percussive rock excavation by hitting a certain point, though there is an effective distance between the slot and blow point; (2) empirical equations are proposed to express the relationship among weight of rock breakage, distance from the slot and depth of the slot, and that among width of rock breakage, distance from the slot and depth of the slot; and (3) an empirical equation expressing the relationship among maximum effective distance from the slot, depth of the slot, and blow energy is proposed. THE ESTIMATION OF PRE-STRESS BY DEFORMATION RATE ANALYSIS AND SUGGESTION OF A MECHANISM FROM THE ELAST-PLASTICAL THEORY [HENKEIRITSU HENKAHO NI YORU SHOKI CHIATSU NO SUITEI TO DANSOSEIGAKUTEKI ICHI KOSATSU]

Manabu Utagawa, Masahiro Seto, and Kunihisa Katsuyama *In its* Journal of NIRE, Volume 2, Number 4 26 Jul. 1993 p 75-8 In JAPANESE (For primary document see N94-28147 07-45)

Avail: CASI HC A02/MF A02

Cyclic loading tests of pre-stressed rocks were conducted to estimate the pre-stress of rocks. In these tests, four strain gages were used to average the inclination of the value of each gage. The results showed a shorter elapsed time after applied pre-stress loading, and a clearer bend of the DRA (Deformation Rate Analysis) curve. With the increase in elapsed time, the DRA curve became less clear. However in that case, the clear bend of the DRA curve appeared at the pre-stress point on and after the second loading. Therefore, it was possible to estimate the pre-stress even when the bend point of the DRA curve was not observed clearly in the first loading. Not only axial prestress but also lateral ones could be estimated for one axial loading test by DRA. The pre-stress estimation method using the DRA curve in cyclic loading is recommended. Also, a theoretical model regarding the bend point of the DRA curve is examined. Author (NASDA)

NUMERICAL SIMULATION OF TURBULENT FREE JET BY TFKE MODEL [TFKE MODERU NI YORU RANRYU JIYU FUNRYU NO SUCHI SHIMYURESHON]

Masakazu Yamazaki and Shinya Kamiyama *In its* Journal of NIRE, Volume 2, Number 4 26 Jul. 1993 p 85-9 In JAPANESE (For primary document see N94-28147 07-45)

Avail: CASI HC A02/MF A02

Free turbulent shear flows such as turbulent jets are characterized by the intermittent phenomenon that rotational and irrotational states appear randomly and separately. In a turbulent jet flame, momentum, mass and heat transport between the fluid fragments of fuel and air resulting from the intermittent fluid motion inside the jet plays a dominant role in determining its structure and combustion characteristics. In this report, the TFKE (Two-Fluid Kappa Epsilon Two-Equation) turbulence model constructed for the prediction of the intermittency by integrating the two-fluid model and kappa epsilon two-equation model is described and the numerical calculations based on the TFKE model for the intermittency and diffusion characteristics of a unburnt axisymmetric turbulent free jet are discussed. It is presented that the numerical predictions satisfy quite well the existing experimental results and the TFKE model can provide the zone averages as well as time averages of the turbulence properties and the length scale distribution. This suggests, therefore, that the TFKE model is one of the promising turbulence models for further numerical simulation of turbulent jet flames. Author (NASDA)

ROLE AND ACTIVITY OF STA ON ASIAN PACIFIC REGIONAL COOPERATION c43

Yoshiaki Takeuchi *In its* Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 5-23 Original contains color illustrations (For primary document see N94-28268 07-45)

Avail: CASI HC A03/MF A03

Promotion of the earth science technology and role and activities on Asian Pacific regional cooperation of the Science and Technology Agency of Japan (STA) are outlined. Topics included are as follows: (1) the National Space Development Agency of Japan (NASDA) and the Japan Marine Science and Technology Center (JAMSTEC) are massive organization for development of the infrastructure necessary for earth observation; (2) STA promotes the research projects in cooperation with other ministries and agencies; (3) STA has two kinds of funds for these research, that is, special funds for investigation and research of earth science and technology and the Special Coordination Funds for Promoting Science and Technology (SCF); (4) intergovernmental cooperation and international cooperation on STA projects; and (5) some projects associated with Asia-Pacific cooperation, such as Japanese Pacific Climate Studies (JAPACS), research program on the changes of tropical forests and their influences, Japan-China Joint Study on Desertification (JC-JOSDES), Japanese experiment on Asian monsoon, and Japanese study on the behavior of greenhouse gases and aerosols. The start of an international cooperative research program on construction of the global data set from FY (Fiscal Year) 1993 with the coordination funds is proposed. Author (NASDA)

COOPERATIVE RESEARCH PROJECTS ON SATELLITE REMOTE SENSING FOR THE HYDROLOGICAL SUBJECTS c43

Shinkichi Kishi *In* Science and Technology Agency, Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 25-3 (For primary document see N94-28268 07-45)
Avail: CASI HC A02/MF A03

Subjects of the cooperative hydrological research projects on satellite remote sensing were outlined. The subjects mentioned are as follows: (1) Japanese Experiment on Asian Monsoon (JEXAM) (1989 to 1998), including studies on air-sea-land interactions and their long term variation and theoretical experimental study by numerical simulations; (2) research for the enhancement of remote sensing technology in earth observation using advanced sensor systems (1992 to 1994); (3) Japan-China Joint Study on Desertification (JC-JOSDES) (1989 to 1992), including studies on the formation of the desert and simulation study on the desertification; and (4) Japanese Pacific Climate Studies (JAPACS) (1990 to 1992), including observation in the sea ice zone and analytical studies on air-sea interaction by the use of the Marine Observation Satellite-1 (MOS-1) data and relevant data. RESEARCH ACTIVITIES ON THE METEOROLOGY OVER THE ASIA-PACIFIC REGION c43

Masato Murakami *In* Science and Technology Agency, Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 33-3 (For primary document see N94-28268 07-45)
Avail: CASI HC A01/MF A03

International joint research projects on the meteorology over Asia-Pacific region, such as the Tropical Ocean Global Atmosphere (TOGA)-Coupled Ocean-Atmosphere Response Experiment (COARE) and the Tropical Rainfall Measuring Mission (TRMM) are outlined. Among the proposed collaboration in the late 1990's, the Global Energy and Water Cycle Experiment (GEWEX) will be the major project which requires both international and interdisciplinary collaboration. GEWEX should pursue the global scale analysis which includes the three dimensional distribution of the wind and water vapor over the ocean, the global climate of clouds and precipitation, the global ocean monitoring and the global monitoring of land and its vegetation. The GEWEX will bring an opportunity to deploy a new earth observing system by satellites in order to monitor, investigate and predict the climate changes. It will give a prototype of the future routine observation network by satellites. In the late 1990's, marine observing satellites related to the TOGA and the World Ocean Circulation Experiment (WOCE) will be realized. Japan should, cooperating with other countries to build up a satellite observation network, develop new sensors capable to observe the important components such as the water vapor, wind, precipitation and the soil moisture over the globe. AN OCEANOGRAPHICAL OBSERVATION IN THE WESTERN PACIFIC AND INTERNATIONAL COOPERATIONS c48

Kei Muneyama *In* Science and Technology Agency, Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 35-4 (For primary document see N94-28268 07-45)
Avail: CASI HC A03/MF A03

Outline of Kuroshio research to study the following subjects are explained: (1) the dynamical oceanography of Kuroshio; (2) the biogeochemical processes; (3) the biological activities; (4) ocean-atmosphere interaction; and (5) development of the observation system. The Japan Marine Science and Technology Center (JAMSTEC) and Badan Pengkajian dan Penerapen Teknologi (BPPT) of Indonesia started a cooperative oceanographical study in waters off Taraud to Halmahera to Irian Java in 1992. The western Pacific is not only the origin of Kuroshio but also the epicenter of El Nino. The warm water is piled up in the western Pacific to form warmpool by the trade wind prevailing in equatorial Pacific. This movement of the convection center eastward means the drought in Southeast Asia and Australia. The role of the Indonesian through-flow has been speculated for past years to be related to the evolution of the warmpool but no direct observation data concerning it's transport volume has been given. The observation of the Indonesian through-flow seems to give valuable data because it has linked directly to the several years scale phenomena such as El Nino and seasonal change such as a monsoon. The most distinctive feature is that the current flows southward at the northern part and flows northward at the southern part at the moment of observation. This result clearly shows the necessity of the seasonal observations. Author (NASDA)

GLOBAL CHANGE AND TERRESTRIAL ECOSYSTEMS (GCTE): PROGRESS REPORT AND PROSPECTS FOR ASIAN CONTRIBUTIONS Progress Report

Will Steffen *In* Science and Technology Agency, Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 131-141 (For primary document see N94-28268 07-45)

Avail: CASI HC A03/MF A03

The objectives and structure of the Global Change and Terrestrial Ecosystems (GCTE) in Australia, its implementation strategy, and the present status are outlined. The topics included are summarized as follows: (1) the objectives of GCTE are to predict the effects of changes in climate, atmospheric composition, and land use on terrestrial ecosystems and to determine how these effects lead to feedbacks to the atmosphere and the physical climate system; and (2) GCTE is organized into a hierarchy of foci, activities, and tasks. The four foci are divided into the ecosystem philosophy, the change in ecosystem structure, the global change impact on agriculture and forestry, and the global change and ecological complexity (proposed). The GCTE operational plan provides the framework for its core research program. The individual projects which contribute to the core research program come primarily from the following two sources: (1) national and regional contributions; and (2) GCTE-initiated research. GCTE has made a strong progress during 1992 with the publication in Apr. 1992 of the GCTE operation plan and the approval of the first set of contributing research projects. A recent meeting of the GCTE Scientific Steering Committee continued the strong progress with the evaluation and acceptance of an additional set of contributing research projects to bring the total of 16 projects involving scientists from 21 countries. There are many opportunities for Asian scientists to contribute to GCTE. Author (NASDA)

GLOBAL CHANGE: A RESEARCH STRATEGY FOR AUSTRALIA 1992-1996 Progress Report

Will Steffen *In* Science and Technology Agency, Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 142-146 (For primary document see N94-28268 07-45)

Avail: CASI HC A01/MF A03

An overview of the current status and new initiatives for the global change program conducted in Australia is presented. The Australian global change research program consists of 10 major projects, each involving a multi-disciplinary team of scientists from several Australian research institutions. The projects are as follows: (1) atmospheric chemistry, biogeochemistry, and ecosystem dynamics in tropical northern Australia; (2) energy and water exchanges between atmosphere and land; (3) impact of changes in carbon dioxide, climate, and land use on agriculture and the environment; (4) ozone depletion and the impact of ultraviolet-B radiation on terrestrial and marine plants; (5) nature and causes of climate change over the past 20,000 years in Australia and Antarctica; (6) past response of vegetation and surface water to Australian climates; (7) circulation, heat transport, and sea ice changes in the southern ocean; (8) eastern Indian Ocean circulation and process study; (9) carbon fluxes in the subtropical convergence and the southern ocean; and (10) the carbon cycle in the monsoonal marine tropics. The present status of and new initiatives for the program are also described. Author (NASDA)

ATMOSPHERIC SCIENCE RESEARCH IN MALAYSIA: PERSPECTIVES ON INTERNATIONAL COOPERATION

Mohammed Ilyas *In* Science and Technology Agency, Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 160-164 (For primary document see N94-28268 07-45)

Avail: CASI HC A01/MF A03

An overview of atmospheric science research in Malaysia is presented. Three institutions playing a key role in atmospheric studies are introduced. Malaysian Meteorological Service is involved in the traditional monitoring and data collection of a wide range of parameters. The Department of Environment is involved in environmental control such as ozone depleting substance control and legislative aspects. The department is also participating in regional and international research programs through the Association of South-East Asian Nations (ASEAN) system, International Geosphere-Biosphere Program (IGBP), World Climate Research Program (WCRP), and World Meteorological Organization. And the University of Science Malaysia is specialized in atmospheric science research. The university is playing a leading role through two major developments. The first one is the physical infrastructure development at the university for a special research focused on atmospheric ozone, minor constituents, and ultraviolet radiation by establishing the Atmospheric Research Unit. The second one is the completion of the Sheikh Tahir Astronomical Observatory to provide a cooperative research base for tropical atmospheric studies. The present status of the tropical network of ozone, ultraviolet (UV), and related atmospheric research and international cooperation is described. Author (NASDA)

HDGEC ACTIVITY IN ASIA PACIFIC REGION

Filomena F. Campos *In* Science and Technology Agency, Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 165-167 Sponsored by Science and Technology Agency and Japan and Research Development Cooperation of Japan (For primary document see N94-28268 07-45)

Avail: CASI HC A01/MF A03

The Human Dimensions of Global Environment Change (HDGEC) activities by the social scientists in close collaboration with the natural scientists are outlined. The following subjects identified by one of the workshop missions during the Global Change System for Analysis, Research, and Training (START) are presented: human dimensions of natural resource management affecting land use change, coastal resource management, and inland resource management; and urbanization and industrialization related to environmental problems. Human response to projected sea level change in Southeastern Asia, one example of global environment change research within the HDGEC, is exemplified. It was agreed by the workshop members that regional collaboration can be strengthened through the following mechanisms: developing closer interaction between the natural and social scientists to establish clear understanding of the integral role of social science in environmental research related to global change; creation of a working group with appropriate representatives in social sciences; establishing and developing a database on socioeconomic and physical science; appointment of social scientists as members of the national International Geosphere-Biosphere Program (IGBP) committee; and inclusion of social scientists in the START organization. Current status of the HDGEC in South Asia is presented. Author (NASDA)

CHANGES IN PHYTOPLANKTON POPULATION IN THE CHAO PHRAYA ESTUARY, THAILAND, DURING THE EUTROPHICATION MECHANISMS STUDIES

Twesukdi Piyakarnchana, S. Boonyapiwat (Ministry of Agriculture and Cooperatives, Bangkok, Thailand.), T. Okaichi (Kagawa Univ., Japan.), S. Wisessang, and G. Wattayakorn *In* Science and Technology Agency, Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 168-191 (For primary document see N94-28268 07-45)
Avail: CASI HC A03/MF A03

The changes in abundance and species compositions of the phytoplankton populations in the estuarine region of the Chao Phraya river mouth were observed. The other environmental parameters such as water temperature, salinity, dissolved oxygen, ammonia, nitrite, nitrate, phosphate, and silicate were also measured. The samples were taken at nine fixed stations within one day, and at one or two selected stations for twenty four hours at every two hours. The results clearly indicate that phytoplankton populations varied with the sampling times and water quality. The number of species compositions in the wet season (August) showed less abundance than in the dry season (December). The differences were greater at the up-river stations with low salinity and high turbidity than at the seaward ones. Phytoplankton species composition differences between wet and dry season and between high and low tide are outlined. Author (NASDA)

LAND USE CHANGE IN THAILAND AND ITS IMPACT ON ENVIRONMENTAL CHANGE: JOINT THAI-JAPANESE RESEARCH PROJECT (1993-1995)

Vanpen Surarerks *In* Science and Technology Agency, Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 192-211 (For primary document see N94-28268 07-45)
Avail: CASI HC A03/MF A03

The significance, background, objectives, methodology, anticipated benefits, and time schedule of the joint Thai-Japanese research project to study land use change and its impact on environmental change are outlined. The objectives are to study and characterize the human activities affecting environmental change, problems in the farming system, and land use, and then to propose suitable land use management. The methodology includes the following subjects: collection of physical and socioeconomic data; data preparation, such as organizing maps for raw data for use in geographic information systems (GIS), tables, models, diagrams, and descriptive data organized from data collected from documents and field surveys; and data analysis, such as mapping from GIS techniques and documentary data interpreted and analyzed as well as data from surveys, observations, and field interviews. Anticipated benefits of recommendations for proposing a suitable land use management at present and in the future, and the time schedule, are presented. Author (NASDA)

STUDY ON ENVIRONMENT MONITORING OVER WHOLE CHINA USING NDVI FROM AVHRR DATA AND FUTURE PROJECT

Zongyi Fang, Qianguang Xiao, Xuanji Wang, and Yongwei Sheng *In* Science and Technology Agency, Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 215-225 Original contains color illustrations (For primary document see N94-28268 07-45)
Avail: CASI HC A03/MF A03

The following aspects of study on environmental monitoring over whole China using Non-Dimensional Vegetation Indices (NDVI) from Advanced Very High-Resolution Radiometer (AVHRR) are outlined: (1) data processing; (2) application analysis; (3) main research contents; (4) subject planning arrangement; and (5) data processing requirements. The following conclusions can be obtained through analysis of remote sensing vegetation indices during the years of 1987 to 1991: (1) the basic conditions for vegetation growth are light, temperature, and water; (2) the climate divisions identified by satellite vegetation index maps match with those identified by temperature; (3) the monthly anomaly of satellite vegetation index matches that of precipitation in general; and (4) the remote sensing monitoring on environment of the vulnerable area is very important because it is quite sensitive to the environmental change. UTILIZATION OF REMOTE SENSING DATA FOR GLOBAL CLIMATE CHANGE RESEARCH IN MALAYSIA

Subramaniam Moten *In* Science and Technology Agency, Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 226-237 (For primary document see N94-28268 07-45)
Avail: CASI HC A03/MF A03

The global climate change research utilizing remote sensing data in Malaysia is presented. The following aspects of global climate change are outlined: (1) greenhouse effect gases and climate change; (2) global warming and its impact on the regional climate; (3) change in rainfall and impacts due to changes of precipitation; (4) change in sea level and impact of sea level rise; (5) utilization of remote sensing data; and (6) remote sensing activities in Malaysia. Global warming affected by increase in greenhouse effect gases is a potential threat to the environment and society. The consequences will be far reaching and the impact will be felt slowly but surely if model simulations are used as indicators. The impact in the tropics may be greater because of increased rainfall during the wet season and possible decrease during the dry season, increase in tropical storm activities and damage to the coastal regions which sustains the economy of many countries. Monitoring the environment is important for checking the trends in climate and detecting changes that are consequences of global warming. Remote sensing can play a useful role by providing data at a high resolution, on timely basis and fraction of the cost for obtaining data from conventional methods. Author (NASDA)

CONTRIBUTION OF SATELLITE OBSERVATION TO GLOBAL CHANGE RESEARCH
Atsushi Takeda *In* Science and Technology Agency, Asia-Pacific Seminar on Global Change Research Cooperation 1992 p 251 (For primary document see N94-28268 07-45)
Avail: CASI HC A01/MF A03

An overview of the contribution of satellite observation to global change research is presented. Satellite observation of the earth can make an outstanding contribution to the research of global change. Satellite observations need to be supplemented by in situ or ground truth observations. Developments in optical sensors are expected to make much improvement in the interpretation of land image. Loss due to cloud cover should be reduced by use of microwave image sensors like Synthetic Aperture Radar (SAR) which can see the earth surface through the cloud layer. Receiving stations and other ground system should also be reinforced particularly in those developing countries and regions. Improved analyzing techniques should be developed quickly to extract more information from the existing data sets and to reduce the cost and time of data processing. Coordination of world satellite programs is strongly recommended to produce effective data sets for global change research of every region over the earth surface. Author (NASDA)

FIBROUS CERAMIC CANDLE FILTER FOR PARTICLE REMOVAL IN PRESSURIZED FLUIDIZED BED COMBUSTION
J. Jalovaara, I. Hippinen, and A. Jahkola Aug. 1993 53 p See also PB94-133071
(PB94-133089; ISBN-951-22-1719-8) Avail: CASI HC A04/MF A01

A fibrous, layered Al2O3/SiO2-based ceramic candle filter has been tested for pressurized fluidized bed combustion (PFBC) hot gas cleaning at the Otaniemi PFBC test rig. The fuels used have been bituminous coal and peat. The exhaust gas from a pressurized fluidized bed reactor was passed through two cyclones before entering the ceramic filter unit, which was operated at a temperature range from 580 to 740 C and at a pressure range from 6 to 10 br (abs.). Total exposure time of the two candle filter elements was about 340 hours. This paper presents measured data and operating experiences of the ceramic filter. NTIS

The highly irregular polar ionosphere requires sophisticated sensing techniques to identify and monitor the ionospheric characteristics. The deployment of a new ionospheric sounder, the Digisonde Portable Sounder (DPS), at Svalbard (78.2 deg N) is described and the first results obtained with this instrument are discussed. The most important new feature in the DPS, not available in the old Digisondes, is the capability of high precision incidence angle measurements and spectral characterization at up to 128 ranges. While Svalbard rotated from the polar cap (at magnetic midnight) through the reversal boundaries and the auroral oval to the cusp region, the DPS was able to monitor the different features of a highly stressed ionosphere. It is demonstrated that the DPS can characterize the behavior of the background ionosphere while simultaneously measuring the motion of irregular plasma structures. This capability can be applied to identify and track irregularities generated by high power HF transmitters as planned for HAARP (HF Active Auroral Research Program) experiments in Alaska. How the DPS identifies different plasma structures in a naturally stressed ionosphere within the field of view of the instrument which extends over several hundred kilometers in the ionosphere is shown. NORWEGIAN IONOSPHERIC SATELLITE EXPERIMENT: HIGH LATITUDE, LOW EARTH ORBIT PLASMA MEASUREMENTS
K. Svenes, B. T. Narheim, J. Troeim, U.-P. Hope, E. V. Thrane, and W. T. Armstrong 15 Apr. 1993 21 p
(FFI-93/7025; ETN-94-95211) Avail: CASI HC A03/MF A01

A possible Norwegian microsatellite is described. It is envisioned that the satellite will be fully developed and tested in Norway. The launch should occur after a short (approximately three years) project period, preferably from Andoya, and operation as well as data archiving should be accomplished in Norway. The main scientific objective of the satellite will be to study ion outflow both from the auroral oval as well as the polar cap. These measurements will in addition be related to the particle precipitation and optical auroral activity in the oval and over the polar cap. A secondary objective will be to do a global survey, with the prerequisite that foreign participation is enlisted for some of the instrument development. ESA

EFFICIENT MODELING IN TRANSVERSELY ISOTROPIC INHOMOGENEOUS MEDIA
T. Alkhalifah Nov. 1993 35 p
(Contract DE-FG02-89ER-14079)
(DE94-003394; DOE/ER-14079/29; CWP-129P) Avail: CASI HC A03/MF A01

An efficient modeling technique for transversely isotropic, inhomogeneous media is developed using a mix of analytical equations and numerical calculations. The analytic equation for the ray path in a factorized transversely isotropic (FTI) media with linear velocity variation, derived by Shearer and Chapman, is used to trace between two points. In addition, an analytical equation is derived for geometrical spreading in FTI media that aids in preserving program efficiency; however, the travel time is calculated numerically. The method is generalized to treat general transversely isotropic (TI) media that are not factorized anisotropic inhomogeneous by perturbing the FTI travel times, following the perturbation ideas of Cerveny and Filho. A Kirchhoff summation based program relying on Trorey's diffraction method is used to generate synthetic seismograms for such a medium. For the type of velocity models treated, the program is much more efficient than finite difference and general ray-trace modeling techniques. DOE

(Contract F19628-91-C-0004)
(AD-A273799; NWRA-CR-93-R092; PL-TR-93-2088) Avail: CASI HC A05/MF A01

Northwest Research Associates (NWRA) has recorded a database containing measurements of the intensities of two L-band signals transmitted by satellites of the Global Positioning System and the differential carrier phase and differential group delay between them. Data collection was carried out during the period Dec. 1990 to Dec. 1992, which immediately followed the recent solar maximum. Data collection equipment, operated and serviced by NWRA, was located at Hanscom AFB, MA; Lerwick, Shetland Island, UK; and Thule AB, Greenland. Software tools to test, quality check, reduce, analyze, and display the data were developed. The total electron content data from the sub-auroral station (Lerwick, Shetland Island, UK) have been well analyzed and are shown to provide extremely detailed morphology for all times, seasons, and levels of magnetic activity. A log detailing the availability of data according to date, site, receiver type, and data quality is included herein. DTIC

INTERACTIONS BETWEEN A TROPICAL MIXED BOUNDARY LAYER AND CUMULUS CONVECTION IN A RADIATIVE-CONVECTIVE MODEL Ph.D. Thesis
C. L. Dean May 1993 142 p Prepared in cooperation with Pennsylvania State Univ., University Park
(Contract DE-AC05-76OR-00033)
(DE94-000848; DOE/OR-00033/T554) Avail: CASI HC A07/MF A02

A radiative-convective model, combining previously developed cumulus, stable cloud and radiation parameterizations with a boundary layer scheme, which was developed in the current study is detailed. The cloud model was modified to incorporate the effects of both small and large clouds. The boundary layer model which was adapted from a mixed layer model was only slightly modified to couple it with the more sophisticated cloud model. The model was tested for a variety of imposed divergence profiles, which simulate the regions of the tropical ocean from approximately the Intertropical Convergence Zone (ITCZ) to the subtropical high region. The sounding used to initialize the model for most of the runs is from the trade wind region of ATEX. For each experiment, the model was run with a timestep of 300 seconds for a period of 7 days. ISOTOPICALLY LABELED CO2 FROM STRATOSPHERE: A TRACER OF CARBON BIOGEOCHEMISTRY
Yuk L. Yung (California Inst. of Tech., Pasadena.) and M. H. Thiemens 1993 4 p
(Contract DE-FC03-90ER-61010)
(DE94-002777; DOE/ER-61010/T14) Avail: CASI HC A01/MF A01

It has been recently discovered that the stratosphere is a source of isotopically enriched CO2: CO(sup 18)O and CO(sup 17)O. The cause of this isotopic enrichment is exchange between heavy O3 and CO2 via the excited radical O((sup 1)D). The research effort consists of a coordinated laboratory and model surfaces of isotopomers of CO2. The laboratory study yields data on the chemical kinetics of oxygen exchange between CO2 and O3. The modeling study uses the laboratory results as well as atmospheric measurements to model the source and sinks of CO2 isotopomers in the stratosphere and troposphere. It is expected that this combined study will bring new insights on the exchange of CO2 between the atmosphere and the biosphere. The goals of this study are to study the kinetic pathways for isotopic exchange between O2 and CO2 and to study O3: the exchange rate of isotopically labelled CO2 between the stratosphere and the troposphere. DOE

LASER ALTIMETRY SIMULATOR. VERSION 3.0: USER'S GUIDE
James B. Abshire, Jan F. McGarry, Linda K. Pacini, J. Bryan Blair, and Gregory C. Elman (Science Systems and Applications, Inc., Lanham, MD.) Jan. 1994 71 p
(NASA-TM-104588; NAS 1.15:104588; Rept-94B00039) Avail: CASI HC A04/MF A01

A numerical simulator of a pulsed, direct detection laser altimeter has been developed to investigate the performance of space-based laser altimeters operating over surfaces with various height profiles. The simulator calculates the laser's optical intensity waveform as it propagates to and is reflected from the terrain surface and is collected by the receiver telescope. It also calculates the signal and noise waveforms output from the receiver's optical detector and waveform digitizer. Both avalanche photodiode and photomultiplier detectors may be selected. Parameters of the detected signal, including energy, the 50 percent rise-time point, the mean timing point, and the centroid, can be collected into histograms and statistics calculated after a number of laser firings. The laser altimeter can be selected to be fixed over the terrain at any altitude. Alternatively, it can move between laser shots to simulate the terrain profile measured with the laser altimeter. QUIET-TIME INTENSIFICATIONS ALONG THE POLEWARD AURORAL BOUNDARY NEAR MIDNIGHT
O. DeLaBeaujardiere, L. R. Lyons, J. M. Ruohoniemi, E. Friis-Christensen, C. Danielsen, F. J. Rich, and P. T. Newel 15 Mar. 1994 15 p
Original contains color illustrations
(ATR-93(7248)-2) Avail: CASI HC A03/MF A01

Radar and optical measurements from Sondrestrom are combined with satellite and Goose Bay data in a study of the poleward edge of the nightside auroral oval during a quiet period. The B(sub y) and B(sub z) components of the interplanetary magnetic field were close to zero, and the B(sub x) component was approximately 8 nT for more than 24 hours. On a large scale, the convection and precipitation patterns remained almost constant during this period; on a small scale, however, the conditions were quite dynamic. At 10- to 20-minute intervals, the arc that marked the poleward auroral boundary intensified, and a new arc appeared poleward of it. About once per hour, stronger intensifications were observed. One such event is examined in detail. The auroral arcs first appeared to dim, and then they brightened, with a factor of ten increase in E region electron density. At the time of the brightening, a new arc formed poleward of all the arcs. The arcs then drifted southward at velocities of approximately 70 m/s. A plasma drift disturbance, characterized by a doubling of the southward velocity and a reversal in the east-west component, propagated westward at 900 m/s through the fields of view of the Sondrestrom and Goose Bay radars. A simultaneous satellite overpass close to the radars revealed the presence of an energetic ion event similar to the 'velocity dispersed ion structures' observed on the Aureol satellite and presumed to be the signature of fast ion beams within the plasma sheet boundary layer. The stronger arc intensification events observed by the Sondrestrom radar are associated with an increase in plasma flow across the boundary between open and closed magnetic field lines. This increased flow is interpreted as the ionospheric signature of abrupt, localized increases in the reconnection rate in the midnight sector. Author (revised)

DYNAMICS EXPLORER INTERDISCIPLINARY SCIENTIST INVESTIGATIONS Final Report, 1 Oct. 1990 - 30 Jan. 1994
Janet U. Kozyra and A. F. Nagy 1994 11 p
(Grant NAG5-472)
(NASA-CR-195226; NAS 1.26:195226; UMICH-021979) Avail: CASI HC A03/MF A01

This document is a final report on research activities and accomplishments that occurred during the funding period of 10-1-90 through 1-30-94. The focus of our interdisciplinary investigation during the Dynamics Explorer Mission was on the complex coupling processes that tap the magnetic-storm energy, stored in the ring current particle reservoir, and transport this energy into the subauroral, midlatitude and even equatorial ionospheric regions. The transport of energy through the inner magnetosphere and into the underlying ionospheric regions is a critical element in our understanding of the impact of solar and magnetic disturbances on upper atmospheric and ionospheric regions equatorward of the auroral zone. IONOSPHERIC MODIFICATION BY HIGH POWER, OBLIQUELY PROPAGATED HF RADIO WAVE TRANSMISSIONS. PART 1: EXPERIMENTAL
Gary S. Sales Jul. 1993 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-90-K-0039)
(AD-A273746; AD-E201706; PL-TR-93-2171-Pt-1; SR-6-Pt-1) Avail: CASI HC A03

Published material on the heating of electrons in the ionosphere using high power transmissions at high frequencies typically used for communications and OTH radar systems is reviewed. Although the emphasis of the reviewed experimental papers involves the oblique nature of radio transmissions, actually the important factor that differentiates these measurements from typical high power plasma heating studies is the fact that these involve underdense heating, i.e., at frequencies above the maximum plasma frequency in the ionosphere. The process of inclusion into this report necessitated a critical judgement of the published experimental results, requiring of them, either a degree of credibility and repeatability or when they have become part of the folk lore in the field of oblique heating. In the latter case, a critical review of the reported results is undertaken in light of the current and best understanding of 'heating' phenomenology. DTIC

EXCITATION OF EARTH-IONOSPHERE WAVEGUIDE IN THE ELF AND LOWER VLF BANDS BY MODULATED IONOSPHERIC CURRENT
E. C. Field and R. M. Bloom 21 May 1993 33 p
(Contract F19628-90-C-0100)
(AD-A274969; SR-3; PL-TR-93-2024) Avail: CASI HC A03/MF A01

In this report, the principal of reciprocity is used in conjunction with a full-wave propagation code to calculate ground-level fields excited by ionospheric currents modulated at frequencies between 50 and 100 Hz with HF heaters. Results show the dependence on source orientation, altitude, and dimension and therefore pertain to experiments using the HIPAS or HAARP ionospheric heaters. In the end-fire mode, the waveguide excitation efficiency of an ELF HED in the ionosphere is up to 20 dB greater than for a ground-based antenna, provided its altitude does not exceed 80 to 90 km. The highest efficiency occurs for a source altitude of around 70 km; if that altitude is raised to 100 km, the efficiency drops by about 20 dB in the day and 10 dB at night. That efficiency does not account for the greater conductivity modulation that might be achieved at altitudes greater than 70 km, however. The trade-off between the altitude dependencies of the excitation efficiency and maximum achievable modulation depends on the ERP of the HF heater, the optimum altitude increasing with increasing ERP. For HIPAS the best modulation altitude is around 70 km, whereas for HAARP there might be marginal value in modulating at attitudes as high as 100 km. DTIC

CRRES HIGH ENERGY PROTON FLUX MAP
M. S. Gussenhoven, E. G. Mullen, C. Hein, J. Bass, and D. Madden Jan. 1994 9 p
(Contract F19628-92-K-0003)
(AD-A274803; PL-TR-94-2004) Avail: CASI HC A02/MF A01

Proton flux maps of near-Earth space are presented using the Proton Telescope (PROTEL) detector on CRRES. The proton energy range covered is 1 - 100 MeV. Contamination of PROTEL measurements due to more than 100 MeV protons is corrected using loss cone data, resulting on consistency with dosimeter measurements and a Monte Carlo computer model of PROTEL. Two states of the inner magnetosphere were found during the CRRES mission, a quiet state having a single proton belt, and an active state with a double belt. The properties of the new population in the second belt are presented. Comparisons with NASA proton codes are made. DTIC

The scattering problem of an arbitrary elastic wave incident upon a spherically symmetric inclusion is considered. General results expressed in the form of canonical scattering coefficients are obtained for the cases of incident P waves and incident S waves. Optical theorems relating the scattering cross-section to the amplitude of the scattered field in the forward direction are also derived for both of these cases. Analytical expressions for scattering coefficients of a homogeneous elastic sphere, a sphere filled by fluid, and a spherical cavity are presented, and scattering cross-sections are calculated for these different types of obstacles. It is shown that the scattering scale factor for low frequencies is defined by the wavelength of the scattered wave rather than the wavelength of the incident wave. Low velocity fluid inclusions have a resonant type of scattering with numerous peaks in the spectrum. Various approximate solutions are derived from the exact solutions, including the low contrast (Born) case and the low frequency (Rayleigh) case. The modifications of the low contrast solution necessary to maintain conservation of energy are discussed. Low-frequency asymptotics of the scattering coefficients for a homogeneous sphere of arbitrary contrast are obtained together with expressions for the scattered fields from both P and S incident waves. These expressions can be used for energy absorbing inclusions by assigning complex values to the elastic parameters. Waves scattered by the earth's core are examined as an example of high-frequency scattering. DTIC

Acoustic Emission (AE) technique was applied to the estimation of fractures and geostress using three kinds of AE measuring systems. One is for measuring AE parameters, other one is for measuring AE waves, and another is for measuring AE parameters in combination with two dimensional source location. The results of the study on the following subjects are as follows: (1) AE measuring systems and experimental consideration on the AE behavior of coal under the compressive stress; (2) experimental considerations on the propagation of hydrofracture in the discontinuous rocks, the propagation of hydrofracture in the coal measure rock, the mechanism of the Kaiser effect of AE, and the effect of elapsed time on the Kaiser effect; and (3) the practical application of the new suggested method to the estimation of geostress using cored rocks. It was confirmed that the new method for estimating geostress using acoustic emission was applicable to the estimation of geostress from cored rocks. Author (NASDA)

The mechanism of stochastic acceleration of the particles in magnetic field and in the field of a wave packet in the conditions of geomagnetic trap is considered. A short survey of the latest works on the problem of stochastic heating of the particles and their resonance interaction with a wave packet in constant magnetic field is given. The simple conclusion of twist mapping is given. DOE

VOLCANOLOGY AND VOLCANIC ACTIVITY WITH A PRIMARY FOCUS ON POTENTIAL HAZARD IMPACTS FOR THE HAWAII GEOTHERMAL PROJECT

R. B. Moore, P. T. Delaney, and J. P. Kauahikaua (Hawaiian Volcano Observatory.) 1993 10 p
(Contract DE-AI05-93OR-22089)
(DE94-001614; DOE/OR-22089/3; USGS-OFR-93-512A) Avail: CASI HC A02/MF A01

This annotated bibliography reviews published references about potential volcanic hazards on the Island of Hawaii that are pertinent to drilling and operating geothermal wells. The first two sections of this annotated bibliography list the most important publications that describe eruptions of Kilauea volcano, with special emphasis on activity in and near the designated geothermal subzones. References about historic eruptions from Mauna Loa's northeast rift zone, as well as the most recent activity on the southern flank of dormant Mauna Kea, adjacent to the Humu'ula Saddle are described. The last section of this annotated bibliography lists the most important publications that describe and analyze deformations of the surface of Kilauea and Mauna Loa volcanoes. DOE
